VOLUME XLV MARCH, 1955 NUMBER ONE

ECONOMIC GROWTH AND INCOME INEQUALITY*

By SIMON KUZNETS

The central theme of this paper is the character and causes of long-term changes in the personal distribution of income. Does inequality in the distribution of income increase or decrease in the course of a country's economic growth? What factors determine the secular level and trends of income inequalities?

These are broad questions in a field of study that has been plagued by looseness in definitions, unusual scarcity of data, and pressures of strongly held opinions. While we cannot completely avoid the resulting difficulties, it may help to specify the characteristics of the size-of-income distributions that we want to examine and the movements of which we want to explain.

Five specifications may be listed. First, the units for which incomes are recorded and grouped should be family-expenditure units, properly adjusted for the number of persons in each—rather than income recipients for whom the relations between receipt and use of income can be widely diverse. Second, the distribution should be complete, *i.e.*, should cover all units in a country rather than a segment either at the upper or lower tail. Third, if possible we should segregate the units whose main income earners are either still in the learning or already in the retired stages of their life cycle—to avoid complicating the picture by including incomes *not* associated with full-time, full-fledged participation in economic activity. Fourth, income should be defined as it is now for national income in this country, *i.e.*, received by individuals, including income in kind, before and after direct taxes, excluding capital gains. Fifth, the units should be grouped by *secular* levels of income, free of cyclical and other transient disturbances.

For such a distribution of mature expenditure units by secular levels

* Presidential address delivered at the Sixty-seventh Annual Meeting of the American Economic Association, Detroit, Michigan, December 29, 1954.

of income per capita, we should measure shares of some fixed ordinal groups—percentiles, deciles, quintiles, etc. In the underlying array the units should be classified by average income levels for a sufficiently long span so that they form income-status groups—say a generation or about 25 years. Within such a period, even when classified by secular income levels, units may shift from one ordinal group to another. It would, therefore, be necessary and useful to study separately the relative share of units that, throughout the generation period of reference, were continuously within a specific ordinal group, and the share of the units that moved into that specific group; and this should be done for the shares of "residents" and "migrants" within all ordinal groups. Without such a long period of reference and the resulting separation between "resident" and "migrant" units at different relative income levels, the very distinction between "low" and "high" income classes loses its meaning, particularly in a study of long-term changes in shares and in inequalities in the distribution. To say, for example, that the "lower" income classes gained or lost during the last twenty years in that their share of total income increased or decreased has meaning only if the units have been classified as members of the "lower" classes throughout those 20 years—and for those who have moved into or out of those classes recently such a statement has no significance.

Furthermore, if one may add a final touch to what is beginning to look like a statistical economist's pipe dream, we should be able to trace secular income levels not only through a single generation but at least through two—connecting the incomes of a given generation with those of its immediate descendants. We could then distinguish units that, throughout a given generation, remain within one ordinal group and whose children—through *their* generation—are also within that group from units that remain within a group through their generation but whose children move up or down on the relative economic scale in their time. The number of possible combinations and permutations becomes large; but it should not obscure the main design of the income structure called for—the classification by long-term income status of a given generation and of its immediate descendants. If living members of society—as producers, consumers, savers, decision-makers on secular problems—react to long-term changes in income levels and shares, data on such an income structure are essential. An economic society can then be judged by the secular level of the income share that it provides for a given generation and for its children. The important corollary is that the study of long-term changes in the income distribution must distinguish between changes in the shares of resident groups—resident within either one or two generations—and changes in the income shares of

groups that, judged by their secular levels, migrate upward or downward on the income scale.

Even if we had data to approximate the income structure just outlined, the broad question posed at the start—how income inequality changes in the process of a country's economic growth—could be answered only for growth under defined economic and social conditions. And, in fact, we shall deal with this question in terms of the experience of the now developed countries which grew under the aegis of the business enterprise. But even with this limitation, there are no statistics that can be used directly for the purpose of measuring the *secular* income structure. Indeed, I have difficulty in visualizing how such information could practicably be collected—a difficulty that may be due to lack of familiarity with the studies of our colleagues in demography and sociology who have concerned themselves with problems of generation or intergeneration mobility and status. But although we now lack data directly relevant to the secular income structure, the setting up of reasonably clear and yet difficult specifications is not merely an exercise in perfectionism. For if these specifications do approximate, and I trust that they do, the real core of our interest when we talk about shares of economic classes or long-term changes in these shares, then proper disclosure of our meaning and intentions is vitally useful. It forces us to examine and evaluate critically the data that are available; it prevents us from jumping to conclusions based on these inadequate data; it reduces the loss and waste of time involved in mechanical manipulations of the type represented by Pareto-curve-fitting to groups of data whose meaning, in terms of income concept, unit of observation, and proportion of the total universe covered, remains distressingly vague; and most important of all, it propels us toward a deliberate construction of testable bridges between the available data and the income structure that is the real focus of our interest.

I. *Trends in Income Inequality*

Forewarned of the difficulties, we turn now to the available data. These data, even when relating to complete populations, invariably classify units by income for a given year. From our standpoint, this is their major limitation. Because the data often do not permit many size-groupings, and because the difference between annual income incidence and longer-term income status has less effect if the number of classes is small and the limits of each class are wide, we use a few wide classes. This does not resolve the difficulty; and there are others due to the scantiness of data for long periods, inadequacy of the unit used—which is, at best, a family and very often a reporting unit—errors in the

data, and so on through a long list. Consequently, the trends in the income structure can be discerned but dimly, and the results considered as preliminary informed guesses.

The data are for the United States, England, and Germany—a scant sample, but at least a starting point for some inferences concerning long-term changes in the presently developed countries. The general conclusion suggested is that the relative distribution of income, as measured by annual income incidence in rather broad classes, has been moving toward equality—with these trends particularly noticeable since the 1920's but beginning perhaps in the period before the first world war.

Let me cite some figures, all for income before direct taxes, in support of this impression. In the United States, in the distribution of income among families (excluding single individuals), the shares of the two lowest quintiles rise from 13½ per cent in 1929 to 18 per cent in the years after the second world war (average of 1944, 1946, 1947, and 1950); whereas the share of the top quintile declines from 55 to 44 per cent, and that of the top 5 per cent from 31 to 20 per cent. In the United Kingdom, the share of the top 5 per cent of units declines from 46 per cent in 1880 to 43 per cent in 1910 or 1913, to 33 per cent in 1929, to 31 per cent in 1938, and to 24 per cent in 1947; the share of the lower 85 per cent remains fairly constant between 1880 and 1913, between 41 and 43 per cent, but then rises to 46 per cent in 1929 and 55 per cent in 1947. In Prussia income inequality increases slightly between 1875 and 1913—the shares of the top quintile rising from 48 to 50 per cent, of the top 5 per cent from 26 to 30 per cent; the share of the lower 60 per cent, however, remains about the same. In Saxony, the change between 1880 and 1913 is minor: the share of the two lowest quintiles declines from 15 to 14½ per cent; that of the third quintile rises from 12 to 13 per cent, of the fourth quintile from 16½ to about 18 per cent; that of the top quintile declines from 56½ to 54½ per cent, and of the top 5 per cent from 34 to 33 per cent. In Germany as a whole, relative income inequality drops fairly sharply from 1913 to the 1920's, apparently due to decimation of large fortunes and property incomes during the war and inflation; but then begins to return to prewar levels during the depression of the 1930's.[1]

[1] The following sources were used in calculating the figures cited.

United States. For recent years we used *Income Distribution by Size, 1944-1950* (Washington, 1953) and Selma Goldsmith and others, "Size Distribution of Income Since the Mid-Thirties," *Rev. Econ Stat*, Feb 1954, XXXVI, 1-32, for 1929, the Brookings Institution data as adjusted in Simon Kuznets, *Shares of Upper Groups in Income and Savings* (New York, 1953), p. 220

United Kingdom. For 1938 and 1947, Dudley Seers, The *Levelling of Income Since 1938*

Even for what they are assumed to represent, let alone as approximations to shares in distributions by secular income levels, the data are such that differences of two or three percentage points cannot be assigned significance. One must judge by the general weight and consensus of the evidence—which unfortunately is limited to a few countries. It justifies a tentative impression of constancy in the relative distribution of income before taxes, followed by some narrowing of relative income inequality after the first world war—or earlier.

Three aspects of this finding should be stressed. First, the data are for income before direct taxes and exclude contributions by government (*e.g.*, relief and free assistance). It is fair to argue that both the proportion and progressivity of direct taxes and the proportion of total income of individuals accounted for by government assistance to the less privileged economic groups have grown during recent decades. This is certainly true of the United States and the United Kingdom, but in the case of Germany is subject to further examination. It follows that the distribution of income after direct taxes and including free contributions by government would show an even greater narrowing of inequality in developed countries with size distributions of pretax, ex-government-benefits income similar to those for the United States and the United Kingdom.

Second, such stability or reduction in the inequality of the percentage shares was accompanied by significant rises in real income per capita. The countries now classified as developed have enjoyed rising per capita incomes except during catastrophic periods such as years of active world conflict. Hence, if the shares of groups classified by their annual income position can be viewed as approximations to shares of groups classified by their secular income levels, a constant percentage share of a given group means that its per capita real income is rising at the same rate as the average for all units in the country; and a reduction in inequality of the shares means that the per capita income of the lower-income groups is rising at a more rapid rate than the per capita income of the upper-income groups.

The third point can be put in the form of a question. Do the distribu-

(Oxford, 1951) p. 39; for 1929, Colin Clark, *National Income and Outlay* (London, 1937) Table 47, p. 109; for 1880, 1910, and 1913, A Bowley, *The Change in the Distribution of the National Income, 1880-1913* (Oxford, 1920)

Germany. For the constituent areas (Prussia, Saxony and others) for years before the first world war, based on S Prokopovich, *National Income of Western European Countries* (published in Moscow in the 1920's). Some summary results are given in Prokopovich, "The Distribution of National Income," *Econ. Jour.*, March 1926, XXXVI, 69-82. See also, "Das Deutsche Volkseinkommen vor und nach dem Kriege," *Einzelschrift zur Stat. des Deutschen Reichs*, no. 24 (Berlin, 1932), and W. S. and E. S. Woytinsky, *World Population and Production* (New York, 1953) Table 192, p. 709.

tions by annual incomes properly reflect trends in distribution by secular incomes? As technology and economic performance rise to higher levels, incomes are less subject to transient disturbances, not necessarily of the cyclical order that can be recognized and allowed for by reference to business cycle chronology, but of a more irregular type. If in the earlier years the economic fortunes of units were subject to greater vicissitudes—poor crops for some farmers, natural calamity losses for some nonfarm business units—if the over-all proportion of individual entrepreneurs whose incomes were subject to such calamities, more yesterday but some even today, was larger in earlier decades, these earlier distributions of income would be more affected by transient disturbances. In these earlier distributions the temporarily unfortunate might crowd the lower quintiles and depress their shares unduly, and the temporarily fortunate might dominate the top quintile and raise its share unduly—proportionately more than in the distributions for later years. If so, distributions by longer-term average incomes might show less reduction in inequality than do the distributions by annual incomes; they might even show an opposite trend.

One may doubt whether this qualification would upset a narrowing of inequality as marked as that for the United States, and in as short a period as twenty-five years. Nor is it likely to affect the persistent downward drift in the spread of the distributions in the United Kingdom. But I must admit a strong element of judgment in deciding how far this qualification modifies the finding of long-term stability followed by reduction in income inequality in the few developed countries for which it is observed or is likely to be revealed by existing data. The important point is that the qualification is relevant; it suggests need for further study if we are to learn much from the available data concerning the secular income structure; and such study is likely to yield results of interest in themselves in their bearing upon the problem of trends in temporal instability of income flows to individual units or to economically significant groups of units in different sectors of the national economy

II. *An Attempt at Explanation*

If the above summary of trends in the secular income structure of developed countries comes perilously close to pure guesswork, an attempt to explain these dimly discernible trends may surely seem foolhardy. Yet it is necessary to do so if only to bring to the surface some factors that may have been at play; induce a search for data bearing upon these factors; and thus confirm or revise our impressions of the trends themselves. Such preliminary speculations are useful

provided it is recognized that we are at a relatively early stage in a long process of interplay among tentative summaries of evidence, preliminary hypotheses, and search for additional evidence that might lead to reformulation and revisions—as bases for new analysis and further search.

The present instalment of initial speculation may be introduced by saying that a long-term constancy, let alone reduction, of inequality in the secular income structure is a puzzle. For there are at least two groups of forces in the long-term operation of developed countries that make for *increasing* inequality in the distribution of income before taxes and excluding contributions by governments. The first group relates to the concentration of savings in the upper-income brackets. According to all recent studies of the apportionment of income between consumption and savings, only the upper-income groups save; the total savings of groups below the top decile are fairly close to zero. For example, the top 5 per cent of units in the United States appear to account for almost two-thirds of individuals' savings; and the top decile comes close to accounting for all of it. What is particularly important is that the inequality in distribution of savings is greater than that in the distribution of property incomes, and hence of assets.[3] Granted that this finding is based on distribution of annual income, and that a distribution by secular levels would show less inequality in income and correspondingly less concentration of savings, the inequality in savings would still remain fairly sharp, perhaps more so than in holdings of assets. Other conditions being equal, the cumulative effect of such inequality in savings would be the concentration of an *increasing* proportion of income-yielding assets in the hands of the upper groups—a basis for larger income shares of these groups and their descendants.

The second source of the puzzle lies in the industrial structure of the income distribution. An invariable accompaniment of growth in developed countries is the shift away from agriculture, a process usually referred to as industrialization and urbanization. The income distribution of the total population, in the simplest model, may therefore be viewed as a combination of the income distributions of the rural and of the urban populations. What little we know of the structures of these two component income distributions reveals that: (a) the average per capita income of the rural population is usually lower than that of the urban;[4] (b) inequality in the percentage shares within the

[3] See Kuznets, *op. cit.*, particularly Chapters 2 and 6

[4] The lower level of per capita income of the agricultural or rural population compared with that of urban is fairly well established, for this country by states, and for many

distribution for the rural population is somewhat narrower than in that for the urban population—even when based on annual income; and this difference would probably be wider for distributions by secular income levels.[4] Operating with this simple model, what conclusions do we reach? First, all other conditions being equal, the increasing weight of urban population means an increasing share for the more unequal of the two component distributions. Second, the relative difference in per capita income between the rural and urban populations does not necessarily drift downward in the process of economic growth: indeed, there is some evidence to suggest that it is stable at best, and tends to widen because per capita productivity in urban pursuits increases more rapidly than in agriculture. If this is so, inequality in the total income distribution should increase.

Two questions then arise: First, why does the share of the top-income groups show no rise over time if the concentration of savings has a cumulative effect? Second, why does income inequality decline and particularly why does the share of the lower-income groups rise if both the weight of the more unequal urban income distribution and the relative difference between per capita urban and per capita rural incomes increase?

The first question has been discussed elsewhere, although the results are still preliminary hypotheses,[5] and it would be impossible to do more here than summarize them briefly.

Factors Counteracting the Concentration of Saving

One group of factors counteracting the cumulative effect of con-

---

other countries (see, *e.g.*, a summary table of closely related measures of product and workers engaged, for various divisions of the productive system, in Colin Clark, *Conditions of Economic Progress*, 2nd ed [London 1951], pp. 316-18). The same table suggests, for the countries with sufficiently long records, a stable or increasing relative difference between per-worker product in agriculture and per-worker product in other sectors of the economy.

[4] This is true of the U S distributions prior to the second world war (see sources cited in footnote 1), in the years after the second world war the difference seems to have disappeared. It is true of the distributions for Prussia, cited by Prokopovich, and most conspicuous for India today as shown in the rough distributions by M Mukherjee and A K Ghosh in "The Pattern of Income and Expenditures in the Indian Union: A Tentative Study," *International Statistical Conferences*, December 1951, Calcutta, India, Part III, pp 49-68.

[5] Some elements of the discussion appeared in "Proportion of Capital Formation to National Product," a paper submitted to the annual meeting of the American Economic Association in 1951 and published in *Am. Econ Rev.*, Proceedings, May 1952, XLII, 507-26. A more elaborate statement is presented in "International Differences in Capital Formation and Financing" (particularly Appendix C, Levels and Trends in Income Shares of Upper Income Groups), a paper submitted to a Conference on Capital Formation and Economic Growth held in 1953 under the auspices of the Universities-National Bureau Committee for Economic Research. It is now in press as part of the volume of proceedings of that conference.

centration of savings upon upper-income shares is legislative interference and "political" decisions. These may be aimed at limiting the cumulation of property directly through inheritance taxes and other explicit capital levies. They may produce similar effects indirectly, *e.g.*, by government-permitted or -induced inflation which reduces the economic value of accumulated wealth stored in fixed-price securities or other properties not fully responsive to price changes; or by legal restriction of the *yield* on accumulated property, as happened recently in the form of rent controls or of artificially low long-term interest rates maintained by the government to protect the market for its own bonds.

To discuss this complex of processes is beyond the competence of this paper, but its existence and possible wide effect should be noted and one point emphasized. All these interventions, even when not directly aimed at limiting the effects of accumulation of past savings in the hands of the few, do reflect the view of society on the long-term utility of wide income inequalities. This view is a vital force that would operate in democratic societies even if there were no other counteracting factors. This should be borne in mind in connection with *changes* in this view even in developed countries, which result from the process of growth and constitute a re-evaluation of the need for income inequalities as a source of savings for economic growth. The result of such changes would be an increasing pressure of legal and political decisions on upper-income shares—increasing as a country moves to higher economic levels.

We turn to three other, less obvious groups of factors countervailing the cumulative effects of concentration of savings. The first is demographic. In the presently developed countries there have been differential rates of increase between the rich and the poor—family control having first spread to the former. Hence, even disregarding migration, one can argue that the top 5 per cent of 1870 and its descendants would account for a significantly smaller percentage of the population in 1920. This is even more likely in a country like the United States with its substantial immigration—usually entering the income distribution at the lower-income levels; and may be less likely in a country from which the poor have emigrated. The top 5 per cent of population in 1920 is, therefore, comprised only partly of the descendants of the top 5 per cent of 1870; perhaps half or a larger fraction must have originated in the lower-income brackets of 1870. This means that the period during which effects of concentration of savings can be assumed to have cumulated to raise the income share of any given fixed ordinal group (whether it be the top 1, 5, or 10 per cent of the population) is much shorter than the fifty years in the span; and hence these effects are much weaker than they would have

been if the top 5 per cent of 1870 had, through their descendants, filled completely the ranks of the top 5 per cent of the population of 1920. Although the cumulative effect of savings may be to raise the relative income of a *progressively diminishing* top proportion of total population, their effect on the relative share of a *fixed* top proportion of the population is much reduced.

The second group of forces resides in the very nature of a dynamic economy with relative freedom of individual opportunity. In such a society technological change is rampant and property assets that originated in older industries almost inevitably have a diminishing proportional weight in the total because of the more rapid growth of younger industries. Unless the descendants of a high-income group manage to shift their accumulating assets into new fields and participate with new entrepreneurs in the growing share of the new and more profitable industries, the long-range returns on their property holdings are likely to be significantly lower than those of the more recent entrants into the class of substantial asset holders. "From shirt-sleeves to shirt-sleeves in three generations" probably exaggerates the effects of this dynamism of a growing economy: there are, among the upper-income groups of today, many descendants of the upper-income groups of more than three or even four generations ago. But the adage is realistic in the sense that a *long unbroken* sequence of connection with rising industries and hence with major sources of continued large property incomes is exceedingly rare; that the successful great entrepreneurs of today are rarely sons of the great and successful entrepreneurs of yesterday.

The third group of factors is suggested by the importance, even in the upper-income brackets, of service income. At any given time, only a limited part of the income differential of a top group is accounted for by the concentration of property yields: much of it comes from the high level of service income (professional and entrepreneurial earnings and the like). The secular rise in the upper incomes due to this source is likely to be less marked than in the service incomes of lower brackets, and for two somewhat different reasons. First in so far as high levels of service incomes of given upper units are due to individual excellence (as is true of many professional and entrepreneurial pursuits), there is much less incentive for and possibility of keeping such incomes at continued high relative levels. Hence, the service incomes of the descendants of an *initially high* level unit are not likely to show as strong an upward trend as the incomes for the large body of population at lower-income levels. Second, a substantial part of the rising trend in per capita income is due to interindustry shift, *i.e.*, a shift of workers from lower-income to higher-income industries. The possibilities of rise

due to such interindustry shifts in the service incomes of the initially high-income groups are much more limited than for the population as a whole: they are already in high-income occupations and industries and the range for them toward higher paid occupations is more narrowly circumscribed.

These three groups of factors, even disregarding such legislative and political intervention as is indicated above, are all characteristics of a dynamic growing economy. The differentials in rate of natural increase between the upper- and the lower-income groups are true only of a rapidly growing population—with or without immigration—but accompanied by declining death rates and declining birth rates, a demographic pattern associated in the past only with the growing Western economies. The impact of new industries on obsolescence of already established wealth as a source of property income is clearly a function of rapid growth, and the more rapid the growth the greater the impact will be. The effect of interindustry shifts on the rise of per capita income, particularly of lower-income groups, is also a function of growth since only in a growing economy is there much shift in the relative importance of the several industrial sectors. One can then say, in general, that the basic factor militating against the rise in upper-income shares that would be produced by the cumulative effects of concentration of savings, is the dynamism of a growing and free economic society.

Yet while the discussion answers the original question, it yields no determinate answer as to whether the trend in income shares of upper groups is upward, downward, or constant. Even for the specific question discussed, a determinate answer depends upon the relative balance of factors—continuous concentration of savings making for an increasing share, and the offsetting forces tending to cancel this effect. To tell what the trend of upper-income shares is likely to be, we need to know much more about the weights of these conflicting pressures. Moreover, the discussion has brought to the surface factors that, in and of themselves, may cause either an upward or a downward trend in the share of upper-income groups and hence in income inequality—in distributions of annual or of secular income. For example, the new entrants into the upper groups—the upward "migrants"—who rise either because of exceptional ability or attachment to new industries or for a variety of other reasons—may be entering the fixed upper group of say the top 5 per cent with an income differential—either annual or long-term—that may be relatively *greater* than that of entrants in the preceding generation. Nothing in the argument so far excludes this possibility—which would mean a rise in the share of upper-income groups, even if the share of the old "resident" part remains constant or

even declines. Even disregarding other factors that will be noted in the next section, no firm conclusion as to trends of upper-income shares can be derived from the bare model discussed. Search for further data might yield evidence that would permit a reasonably rough but determinate conclusion; but I have no such evidence at hand.

The Shift from Agricultural to Nonagricultural Sectors

What about the trend toward greater inequality due to the shift from the agricultural to the nonagricultural sectors? In view of the importance of industrialization and urbanization in the process of economic growth, their implications for trends in the income distribution should be explored—even though we have neither the necessary data nor a reasonably complete theoretical model.

The implications can be brought out most clearly with the help of a numerical illustration (see Table I). In this illustration we deal with two sectors: agriculture (A) and all others (B). For each sector we assume percentage distributions of total sector income among sector deciles: one distribution (*E*) is of moderate inequality, with the shares starting at 5.5 per cent for the lowest decile and rising 1 percentage point from decile to decile to reach 14.5 per cent for the top decile; the other distribution (*U*) is much more unequal, the shares starting at 1 per cent for the lowest decile, and rising 2 percentage points from decile to decile to reach 19 per cent for the top decile. We assign per capita incomes to each sector: 50 units to A and 100 units to B in case I (lines 1-10 in the illustration): 50 to A and 200 to B in case II (lines 11-20). Finally, we allow the proportion of the numbers in sector A in the total number to decline from 0.8 to 0.2.

The numerical illustration is only a partial summary of the calculations, showing the shares of the lowest and highest quintiles in the income distribution for the total population under different assumptions.[6] The basic assumptions used throughout are that the per capita income of sector B (nonagricultural) is always higher than that of sector A; that the proportion of sector A in the total number declines; and that the inequality of the income distribution within sector A may be as wide as that within sector B but not wider. With the assumptions con-

[6] The underlying calculations are quite simple For each case we distinguish 20 cells within the total distribution—sets of ten deciles for each sector For each cell we compute the percentage shares of both number and income in the number and income of total population, and hence also the relative per capita income of each cell. The cells are then arrayed in increasing order of their relative per capita income and cumulated. In the resulting cumulative distributions of number and countrywide income we establish, by arithmetic interpolation, if interpolation is needed, the percentage shares in total income of the successive quintiles of the country's population.

TABLE I.—PERCENTAGE SHARES OF 1ST AND 5TH QUINTILES IN THE INCOME DISTRIBUTION FOR TOTAL POPULATION UNDER VARYING ASSUMPTIONS CONCERNING PER CAPITA INCOME WITHIN THE SECTORS, PROPORTIONS OF SECTORS IN TOTAL NUMBER, AND INTRASECTOR INCOME DISTRIBUTIONS

	Proportion of Number in Sector A to Total Number						
	0.8 (1)	0.7 (2)	0.6 (3)	0.5 (4)	0.4 (5)	0.3 (6)	0.2 (7)
I. Per Capita Income of Sector A = 50; of Sector B = 100							
1. Per capita income of total population	60	65	70	75	80	85	90
Distribution (*E*) for Both Sectors							
2. Share of 1st quintile	10.5	9.9	9.6	9.3	9.4	9.8	10.2
3. Share of 5th quintile	34.2	35.8	35.7	34.7	33.2	31.9	30.4
4. Range (3-2)	23.7	25.9	26.1	25.3	23.9	22.1	20.2
Distribution (*U*) for Both Sectors							
5. Share of 1st quintile	3.8	3.8	3.7	3.7	3.8	3.8	3.9
6. Share of 5th quintile	40.7	41.9	42.9	42.7	41.5	40.2	38.7
7. Range (6-5)	36.8	38.1	39.1	39.0	37.8	36.4	34.8
Distribution (*E*) for Sector A, (*U*) for Sector B							
8. Share of 1st quintile	9.3	8.3	7.4	6.7	6.0	5.4	4.9
9. Share of 5th quintile	37.7	41.0	42.9	42.7	41.5	40.2	38.7
10. Range (9-8)	28.3	32.7	35.4	36.0	35.5	34.8	33.8
I. Per Capita Income of Sector A = 50; of Sector B = 200							
11. Per capita income of total population	80	95	110	125	140	155	170
Distribution (*E*) for Both Sectors							
12. Share of 1st quintile	7.9	6.8	6.1	5.6	5.4	5.4	5.9
13. Share of 5th quintile	50.0	49.1	45.5	41.6	38.0	35.0	32.2
14. Range (13-12)	42.1	42.3	39.4	36.0	32.6	29.6	26.3
Distribution (*U*) for Both Sectors							
15. Share of 1st quintile	3.1	2.9	2.7	2.6	2.6	2.7	3.1
16. Share of 5th quintile	52.7	56.0	54.5	51.2	47.4	44.1	40.9
17. Range (16-15)	49.6	53.1	51.8	48.6	44.8	41.4	37.9
Distribution (*E*) for Sector A, (*U*) for Sector B							
18. Share of 1st quintile	7.4	6.2	5.4	4.7	4.2	3.9	3.8
19. Share of 5th quintile	51.6	56.0	54.6	51.2	47.4	44.1	40.9
20. Range (19-18)	44.2	49.8	49.2	46.5	43.2	40.2	37.2

For methods of calculating the shares of quintiles, see text (p. 12 and fn 6). Some differences rill not check because of rounding.

:erning three sets of factors—intersector differences in per capita in- :ome, intrasector distributions, and sector weights—varying within the imitations just indicated, the following conclusions are suggested:

First, if the per capita income differential increases, or if the income distribution is more unequal for sector B than for sector A, or if both conditions are present, the rise over time in the relative weight of sector B causes a marked increase in inequality in the countrywide income distribution. We have here a demonstration of the effects upon trends in income inequality of interindustry shifts away from agriculture discussed above (pp. 7-8).

Second, if the intrasector income distribution is the same for both sectors, and the widening inequality in the countrywide income distribution is due only to the increasing per capita income differential in favor of sector B, such widening is greater when the intrasector income distributions are characterized by moderate rather than wide inequality. Thus, if the intrasector distributions are of the *E* type, the range in the countrywide distribution widens from 23.7 to 26.3 as proportion of A drops from 0.8 to 0.2 and as the ratio of per capita income of sector B to that of sector A changes from 2 to 4 (see line 4, col. 1, and line 14, col. 7). If the *U* distributions are used, the range, under identical conditions, widens only from 36.8 to 37.9 (see line 7, col. 1, and line 17, col. 7). This difference is revealed more clearly by the change in the share of the 1st quintile, which bears the brunt of widening inequality: for the *E* distribution, the share drops from 10.5 (line 2, col. 1) to 5.9 (line 12, col. 7); for the *U* distribution, from 3.8 (line 5, col. 1) to 3.1 (line 15, col. 7).

Third, if the per capita income differential between sectors is constant, but the intrasector distribution of B is more unequal than that of A, the widening inequality in the countrywide distribution is the greater, the lower the assumed per capita income differential. Thus for a differential of 2 to 1, the range widens from 28.3 when the proportion of A is 0.8 (line 10, col 1) to 36.0 at the peak when the proportion of A is 0.5 (line 10 col. 4) and is still 35.8 when the proportion of A drops to 0.2 (line 10, col. 7). For a per capita income differential of 4 to 1, the widening of the range at the maximum is only from 44.2 (line 20, col. 1) to 49.8 (line 20, col. 2) and then the range declines to 37.2 (line 20, col. 7), well below the initial level.

Fourth, the assumptions utilized in the numerical illustration —of a rise in proportions of total number in section B, of greater inequality in the distribution within sector B, and of the growing excess of per capita income in B over that in A—yield a decline in the share of the 1st quintile that is much more conspicuous than the rise in the share of the 5th quintile. Thus the share of the 1st quintile, with the proportion of A at 0.8, distribution in B more unequal than in A, and a per capita income differential of 2 to 1, is 9.3 (line 8, col. 1). As we shift to a proportion of A of 0.2, and a per capita income differential of 4 to 1, the

share of the 1st quintile drops to 3.8 (line 18, col. 7). Under the same conditions, the share of the 5th quintile changes from 37.7 (line 9, col. 1) to 40.9 (line 19, col. 7).

Fifth, even if the differential in per capita income between the two sectors remains constant and the intrasector distributions are identical for the two sectors, the mere shift in the proportions of numbers produces slight but significant changes in the distribution for the country as a whole. In general, as the proportion of A drifts from 0.8 downwards, the range tends first to widen and then to diminish. When the per capita income differential is low (2 to 1), the widening of the range reaches a peak close to middle of the series, *i.e.*, at a proportion of A equal to 0.6 (lines 4 and 7); and the movements in the range tend to be rather limited. When the per capita income differential is large (4 to 1), the range contracts as soon as the proportion of A passes the level of 0.7, and the decline in the range is quite substantial (lines 14 and 17).

Sixth, of particular bearing upon the shares of upper-income groups is the finding that the share of the top quintile declines as the proportion of A falls below a certain, rather high fraction of total numbers. There is not a single case in the illustration in which the share of the 5th quintile fails to decline, either throughout or through a substantial segment of the sequence in the downward movement of the proportion of A from 0.8 to 0.2. In lines 6 and 9, the share of the 5th quintile declines beyond the point at which the proportion of A is 0.6; and in all other relevant lines the downward trend in the share of the 5th quintile sets in earlier. The reason lies, of course, in the fact that with increasing industrialization, the growing weight of the nonagricultural sector, with its higher per capita income, raises the per capita income for the whole economy; and yet per capita income within each sector and the intrasector distributions are kept constant. Under such conditions, the upper shares would fail to decline only if there were either a greater rise in per capita income of sector B than in that of sector A; or increasing inequality in the intrasector distribution of sector B.

Several other conjectural conclusions could be drawn with additional variations in assumptions, and multiplication of sectors beyond the two distinguished in the numerical illustration. But even in the simple model illustrated the variety of possible patterns is impressive; and one is forced to the view that much more empirical information is needed to permit a proper choice of specific assumptions and constants. Granted that several of the conclusions could be generalized in formal mathematical terms, useful inferences would be within our reach only if we knew more about the specific sector distributions and the levels and trends in per capita income differentials among the sectors.

If then we limit ourselves to what is known or can be plausibly as-

sumed, the following inferences can be suggested. We know that per capita income is greater in sector B than in sector A; that, at best, the per capita income differential between sectors A and B has been fairly constant (*e.g.*, in the United States) and has perhaps more often increased; that the proportion of sector A in total numbers has diminished. Then, if we start with intrasector distribution of B more unequal than for A, we would expect results suggested by either lines 8-10 or 18-20. In the former case, the range widens as the proportion of A drops from 0.8 to 0.5, and then narrows. In the latter case, the range declines beyond the point at which the proportion of A is 0.7. But in both cases, the share of the 1st quintile declines, and fairly appreciably and continuously (see lines 8 and 18). The magnitude and continuity of the decline are partly the result of the specific assumptions made; but one would be justified in arguing that within the broad limits suggested by the illustration, the assumption of greater inequality in the intrasector distribution for sector B than for sector A, yields a downward trend in the share of the lower-income groups. Yet we find no such trend in the empirical evidence that we have. Can we assume that in the earlier periods the internal distribution for sector B was not more unequal than for sector A, despite the more recent indications that urban income distribution is more unequal than the rural?

There is, obviously, room for conjecture. It seems most plausible to assume that in earlier periods of industrialization, even when the nonagricultural population was still relatively small in the total, its income distribution was more unequal than that of the agricultural population. This would be particularly so during the periods when industrialization and urbanization were proceeding apace and the urban population was being swelled, and fairly rapidly, by immigrants—either from the country's agricultural areas or from abroad. Under these conditions, the urban population would run the full gamut from low-income positions of recent entrants to the economic peaks of the established top-income groups. The urban income inequalities might be assumed to be far wider than those for the agricultural population which was organized in relatively small individual enterprises (large-scale units were rarer then than now).

If we grant the assumption of wider inequality of distribution in sector B, the shares of the lower-income brackets should have shown a downward trend. Yet the earlier summary of empirical evidence indicates that during the last 50 to 75 years there has been no widening in income inequality in the developed countries but, on the contrary, some narrowing within the last two to four decades. It follows that the intrasector distribution—either for sector A or for sector B—must have shown sufficient narrowing of inequality to offset the increase called

for by the factors discussed. Specifically, the shares of the *lower* income groups in sectors A and/or B must have increased sufficiently to offset the decline that would otherwise have been produced by a combination of the elements shown in the numerical illustration.

This narrowing in inequality, the offsetting rise in the shares of the lower brackets, most likely occurred in the income distribution for the urban groups, in sector B. While it may also have been present in sector A, it would have had a more limited effect on the inequality in the countrywide income distribution because of the rapidly diminishing weight of sector A in the total. Nor was such a narrowing of income inequality in agriculture likely: with industrialization, a higher level of technology permitted larger-scale units and, in the United States for example, sharpened the contrast between the large and successful business farmers and the subsistence sharecroppers of the South. Furthermore, since we accept the assumption of *initially* narrower inequality in the internal distribution of income in sector A than in sector B, any significant reduction in inequality in the former is less likely than in the latter.

Hence we may conclude that the major offset to the widening of income inequality associated with the shift from agriculture and the countryside to industry and the city must have been a rise in the income share of the lower groups within the nonagricultural sector of the population. This provides a lead for exploration in what seems to me a most promising direction: consideration of the pace and character of the economic growth of the urban population, with particular reference to the relative position of lower-income groups. Much is to be said for the notion that once the early turbulent phases of industrialization and urbanization had passed, a variety of forces converged to bolster the economic position of the lower-income groups within the urban population. The very fact that after a while, an increasing proportion of the urban population was "native," *i.e.*, born in cities rather than in the rural areas, and hence more able to take advantage of the possibilities of city life in preparation for the economic struggle, meant a better chance for organization and adaptation, a better basis for securing greater income shares than was possible for the newly "immigrant" population coming from the countryside or from abroad. The increasing efficiency of the older, established urban population should also be taken into account. Furthermore, in democratic societies the growing political power of the urban lower-income groups led to a variety of protective and supporting legislation, much of it aimed to counteract the worst effects of rapid industrialization and urbanization and to support the claims of the broad masses for more adequate shares of the growing income of the country. Space does not permit the discussion of demographic, political, and social considerations that could be brought

to bear to explain the offsets to any declines in the shares of the lower groups, declines otherwise deducible from the trends suggested in the numerical illustration.

III. *Other Trends Related to Those in Income Inequality*

One aspect of the conjectural conclusion just reached deserves emphasis because of its possible interrelation with other important elements in the process and theory of economic growth. The scanty empirical evidence suggests that the narrowing of income inequality in the developed countries is relatively recent and probably did not characterize the earlier stages of their growth. Likewise, the various factors that have been suggested above would explain stability and narrowing in income inequality in the later rather than in the earlier phases of industrialization and urbanization. Indeed, they would suggest widening inequality in these early phases of economic growth, especially in the older countries where the emergence of the new industrial system had shattering effects on long-established pre-industrial economic and social institutions. This timing characteristic is particularly applicable to factors bearing upon the lower-income groups: the dislocating effects of the agricultural and industrial revolutions, combined with the "swarming" of population incident upon a rapid decline in death rates and the maintenance or even rise of birth rates, would be unfavorable to the relative economic position of lower-income groups. Furthermore, there may also have been a preponderance in the earlier periods of factors favoring maintenance or increase in the shares of top-income groups: in so far as their position was bolstered by gains arising out of new industries, by an unusually rapid rate of creation of new fortunes, we would expect these forces to be relatively stronger in the early phases of industrialization than in the later when the pace of industrial growth slackens.

One might thus assume a long swing in the inequality characterizing the secular income structure: widening in the early phases of economic growth when the transition from the pre-industrial to the industrial civilization was most rapid, becoming stabilized for a while, and then narrowing in the later phases. This long secular swing would be most pronounced for older countries where the dislocation effects of the earlier phases of modern economic growth were most conspicuous; but it might be found also in the "younger" countries like the United States, if the period preceding marked industrialization could be compared with the early phases of industrialization, and if the latter could be compared with the subsequent phases of greater maturity.

If there is some evidence for assuming this long swing in relative inequality in the distribution of income before direct taxes and exclud-

ing free benefits from government, there is surely a stronger case for assuming a long swing in inequality of income net of direct taxes and including government benefits. Progressivity of income taxes and, indeed, their very importance characterize only the more recent phases of development of the presently developed countries; in narrowing income inequality they must have accentuated the downward phase of the long swing, contributing to the reversal of trend in the secular widening and narrowing of income inequality.

No adequate empirical evidence is available for checking this conjecture of a long secular swing in income inequality;[7] nor can the phases be dated precisely. However, to make it more specific, I would place the early phase in which income inequality might have been widening, from about 1780 to 1850 in England; from about 1840 to 1890, and particularly from 1870 on in the United States; and, from the 1840's to the 1890's in Germany. I would put the phase of narrowing income inequality somewhat later in the United States and Germany than in England—perhaps beginning with the first world war in the former and in the last quarter of the 19th century in the latter.

Is there a possible relation between this secular swing in income inequality and the long swing in other important components of the growth process? For the older countries a long swing is observed in the rate of growth of population—the upward phase represented by acceleration in the rate of growth reflecting the early reduction in the death rate which was not offset by a decline in the birth rate (and in some cases was accompanied by a rise in the birth rate); and the downward phase represented by a shrinking in the rate of growth reflecting the more pronounced downward trend in the birth rate. Again, in the older countries, and also perhaps in the younger, there may have been a secular swing in the rate of urbanization, in the sense that the proportional additions to urban population and the measures of internal migration that produced this shift of population probably increased for a while—from the earlier much lower levels; but then tended to diminish as urban population came to dominate the country and as the rural reservoirs of migration became proportionally much smaller. For old, and perhaps for young countries also, there must have been a secular swing in the proportions of savings or capital formation to total economic product. Per capita product in pre-industrial times was not large enough to permit as high a nationwide rate of saving or capital formation as was attained in the course of industrial development: this is

[7] Prokopovich's data on Prussia, from the source cited in footnote 1, indicate a substantial widening in income inequality in the early period. The share of the lower 90 per cent of the population declines from 73 per cent in 1854 to 65 per cent in 1875; the share of the top 5 per cent rises from 21 to 25 per cent. But I do not know enough about the data for the early years to evaluate the reliability of the finding

suggested by present comparisons between net capital formation rates of 3 to 5 per cent of national product in underdeveloped countries and rates of 10 to 15 per cent in developed countries. If then, at least in the older countries, and perhaps even in the younger ones—prior to initiation of the process of modern development—we begin with low secular levels in the savings proportions, there would be a rise in the early phases to appreciably higher levels. We also know that during recent periods the net capital formation proportion and even the gross, failed to rise and perhaps even declined.

Other trends might be suggested that would possibly trace long swings similar to those for inequality in income structure, rate of growth of population, rate of urbanization and internal migration, and the proportion of savings or capital formation to national product. For example, such swings might be found in the ratio of foreign trade to domestic activities; in the aspects, if we could only measure them properly, of government activity that bear upon market forces (there must have been a phase of increasing freedom of market forces, giving way to greater intervention by government). But the suggestions already made suffice to indicate that the long swing in income inequality must be viewed as part of a wider process of economic growth, and interrelated with similar movements in other elements. The long alternation in the rate of growth of population can be seen partly as a cause, partly as an effect of the long swing in income inequality which was associated with a secular rise in real per capita income levels. The long swing in income inequality is also probably closely associated with the swing in capital formation proportions—in so far as wider inequality makes for higher, and narrower inequality for lower, country-wide savings proportions.

IV. *Comparison of Developed and Underdeveloped Countries*

What is the bearing of the experience of the developed countries upon the economic growth of underdeveloped countries? Let us examine briefly the data on income distribution in the latter, and speculate upon some of the implications.

As might have been expected, such data for underdeveloped countries are scanty. For the present purpose distributions of family income for India in 1949-50, for Ceylon in 1950, and for Puerto Rico in 1948 were used. While the coverage is narrow and the margin of error wide, the data show that income distribution in these underdeveloped countries is somewhat *more* unequal than in the developed countries during the period after the second world war. Thus the shares of the lower 3 quintiles are 28 per cent in India, 30 per cent in Ceylon, and 24 per cent in Puerto Rico—compared with 34 per cent in the United States and 36

per cent in the United Kingdom. The shares of the top quintile are 55 per cent in India, 50 per cent in Ceylon, and 56 per cent in Puerto Rico, compared with 44 per cent in the United States and 45 per cent in the United Kingdom.[8]

This comparison is for income before direct taxes and excluding free benefits from governments. Since the burden and progressivity of direct taxes are much greater in developed countries, and since it is in the latter that substantial volumes of free economic assistance are extended to the lower-income groups, a comparison in terms of income net of direct taxes and including government benefits would only accentuate the wider inequality of income distributions in the underdeveloped countries. Is this difference a reliable reflection of wider inequality also in the distribution of *secular* income levels in underdeveloped countries? Even disregarding the margins of error in the data, the possibility raised earlier in this paper that transient disturbances in income levels may be more conspicuous under conditions of primitive material and economic technology would affect the comparison just made. Since the distributions cited reflect the annual income levels, a greater allowance should perhaps be made for transient disturbances in the distributions for the underdeveloped than in those for the developed countries. Whether such a correction would obliterate the difference is a matter on which I have no relevant evidence.

Another consideration might tend to support this qualification. Underdeveloped countries are characterized by low average levels of income per capita, low enough to raise the question how the populations manage to survive. Let us assume that these countries represent fairly unified population groups, and exclude, for the moment, areas that combine large native populations with small enclaves of nonnative, privileged minorities, *e.g.*, Kenya and Rhodesia, where income inequality, because of the excessively high income shares of the privileged minority, is appreciably wider than even in the underdeveloped countries cited above.[9] On this assumption, one may infer that in countries

[8] For sources of these data see "Regional Economic Trends and Levels of Living," submitted at the Norman Waite Harris Foundation Institute of the University of Chicago in November 1954 (in press in the volume of proceedings). This paper, and an earlier one, "Underdeveloped Countries and the Pre-industrial Phases in the Advanced Countries: An Attempt at Comparison," prepared for the World Population Meetings in Rome held in September 1954 (in press) discuss issues raised in this section.

[9] In one year since the second world war, the non-African group in Southern Rhodesia, which accounted for only 5 per cent of total population, received 57 per cent of total income; in Kenya, the minority of only 2.9 per cent of total population, received 51 per cent of total income; in Northern Rhodesia, the minority of only 1.4 per cent of total population, received 45 per cent of total income. See United Nations, *National Income and Its Distribution in Underdeveloped Countries*, Statistical Paper, Ser. F, no. 3, 1951, Table 12, p. 19.

with low average income, the secular level of income in the lower brackets could not be below a fairly sizable proportion of average income—otherwise, the groups could not survive. This means, to use a purely hypothetical figure, that the secular level of the share of the lowest decile could not fall far short of 6 or 7 per cent, *i.e.*, the lowest decile could not have a per capita income less than six- or seven-tenths of the countrywide average. In more advanced countries, with higher average per capita incomes, even the *secular* share of the lowest bracket could easily be a smaller fraction of the countrywide average, say as small as 2 or 3 per cent for the lowest decile, *i.e.*, from a fifth to a third of the countrywide average—without implying a materially impossible economic position for that group. To be sure, there is in all countries continuous pressure to raise the relative position of the bottom-income groups; but the fact remains that the lower limit of the proportional share in the secular income structure is higher when the real countrywide per capita income is low than when it is high.

If the long-term share of the lower-income groups is larger in the underdeveloped than in the average countries, income inequality in the former should be narrower, not wider as we have found. However, if the lower brackets receive larger shares, and at the same time the very top brackets also receive larger shares—which would mean that the intermediate income classes would not show as great a progression from the bottom—the net effect may well be wider inequality. To illustrate, let us compare the distributions for India and the United States. The first quintile in India receives 8 per cent of total income, more than the 6 per cent share of the first quintile in the United States. But the second quintile in India receives only 9 per cent, the third 11, and the fourth 16; whereas in the United States, the shares of these quintiles are 12, 16, and 22 respectively. This is a rough statistical reflection of a fairly common observation relating to income distributions in underdeveloped compared with developed countries. The former have no "middle" classes: there is a sharp contrast between the preponderant proportion of population whose average income is well below the generally low countrywide average, and a small top group with a very large relative income excess. The developed countries, on the other hand, are characterized by a much more gradual rise from low to high shares, with substantial groups receiving more than the high countrywide income average, and the top groups securing smaller shares than the comparable ordinal groups in underdeveloped countries.

It is, therefore, possible that even the distributions of secular income levels would be more unequal in underdeveloped than in developed countries—not in the sense that the shares of the lower brackets would be lower in the former than in the latter, but in the sense that the shares

of the very top groups would be higher and that those of the groups below the top would all be significantly lower than a low countrywide income average. This is even more likely to be true of the distribution of income net of direct taxes and inclusive of free government benefits. But whether a high probability weight can be attached to this conjecture is a matter for further study.

In the absence of evidence to the contrary, I assume that it is true: that the secular income structure is somewhat more unequal in underdeveloped countries than in the more advanced—particularly in those of Western and Northern Europe and their economically developed descendants in the New World (the United States, Canada, Australia, and New Zealand). This conclusion has a variety of important implications and leads to some pregnant questions, of which only a few can be stated here.

In the first place, the wider inequality in the secular income structure of underdeveloped countries is associated with a much lower level of average income per capita. Two corollaries follow—and they would follow even if the income inequalities were of the same relative range in the two groups of countries. First, the impact is far sharper in the underdeveloped countries, where the failure to reach an already low countrywide average spells much greater material and psychological misery than similar proportional deviations from the average in the richer, more advanced countries. Second, positive savings are obviously possible only at much higher relative income levels in the underdeveloped countries: if in the more advanced countries some savings are possible in the fourth quintile, in the underdeveloped countries savings could be realized only at the very peak of the income pyramid, say by the top 5 or 3 per cent. If so, the concentration of savings and of assets is even more pronounced than in the developed countries; and the effects of such concentration in the past may serve to explain the peculiar characteristics of the secular income structure in underdeveloped countries today.

The second implication is that this unequal income structure presumably coexisted with a low rate of growth of income per capita. The underdeveloped countries today have not always lagged behind the presently developed areas in level of economic performance; indeed, some of the former may have been the economic leaders of the world in the centuries preceding the last two. The countries of Latin America, Africa, and particularly those of Asia, are underdeveloped today because in the last two centuries, and even in recent decades, their rate of economic growth has been far lower than that in the Western World—and low indeed, if any growth there was, on a per capita basis. The underlying shifts in industrial structure, the opportunities for internal

mobility and for economic improvement, were far more limited than in the more rapidly growing countries now in the developed category. There was no hope, within the lifetime of a generation, of a significantly perceptible rise in the level of real income, or even that the next generation might fare much better. It was this hope that served as an important and realistic compensation for the wide inequality in income distribution that characterized the presently developed countries during the earlier phases of their growth.

The third implication follows from the preceding two. It is quite possible that income inequality has not narrowed in the underdeveloped countries within recent decades. There is no empirical evidence to check this conjectural implication, but it is suggested by the absence, in these areas, of the dynamic forces associated with rapid growth that in the developed countries checked the upward trend of the upper-income shares that was due to the cumulative effect of continuous concentration of past savings; and it is also indicated by the failure of the political and social systems of underdeveloped countries to initiate the governmental or political practices that effectively bolster the weak positions of the lower-income classes. Indeed, there is a possibility that inequality in the secular income structure of underdeveloped countries may have widened in recent decades—the only qualification being that where there has been a recent shift from colonial to independent status, a privileged, *nonnative* minority may have been eliminated. But the implication, in terms of the income distribution among the *native* population proper, still remains plausible.

The somber picture just presented may be an oversimplified one. But I believe that it is sufficiently realistic to lend weight to the questions it poses—questions as to the bearing of the recent levels and trends in income inequality, and the factors that determine them, upon the future prospect of underdeveloped countries within the orbit of the free world.

The questions are difficult, but they must be faced unless we are willing completely to disregard past experience or to extrapolate mechanically oversimplified impressions of past development. The first question is: Is the pattern of the older developed countries likely to be repeated in the sense that in the early phases of industrialization in the underdeveloped countries income inequalities will tend to widen before the leveling forces become strong enough first to stabilize and then reduce income inequalities? While the future cannot be an exact repetition of the past, there are already certain elements in the present conditions of underdeveloped societies, *e.g.*, "swarming" of population due to sharp cuts in death rates unaccompanied by declines in birth rates—that threaten to widen inequality by depressing the relative position of lower-income groups even further. Furthermore, if and when industrialization

begins, the dislocating effects on these societies, in which there is often an old hardened crust of economic and social institutions, are likely to to be quite sharp—so sharp as to destroy the positions of some of the lower groups more rapidly than opportunities elsewhere in the economy may be created for them.

The next question follows from an affirmative answer to the first. Can the political framework of the underdeveloped societies withstand the strain which further widening of income inequality is likely to generate? This query is pertinent if it is realized that the real per capita income level of many underdeveloped societies today is lower than the per capita income level of the presently developed societies before *their* initial phases of industrialization. And yet the stresses of the dislocations incident to early phases of industrialization in the developed countries were sufficiently acute to strain the political and social fabric of society, force major political reforms, and sometimes result in civil war.

The answer to the second question may be negative, even granted that industrialization may be accompanied by a rise in real per capita product. If, for many groups in society, the rise is even partly offset by a decline in their proportional share in total product; if, consequently, it is accompanied by widening of income inequality, the resulting pressures and conflicts may necessitate drastic changes in social and political organization. This gives rise to the next and crucial question: How can either the institutional and political framework of the underdeveloped societies or the processes of economic growth and industrialization be modified to favor a sustained rise to higher levels of economic performance and yet avoid the fatally simple remedy of an authoritarian regime that would use the population as cannon-fodder in the fight for economic achievement? How to minimize the cost of transition and avoid paying the heavy price—in internal tensions, in long-run inefficiency in providing means for satisfying wants of human beings as individuals—which the inflation of political power represented by authoritarian regimes requires?

Facing these acute problems, one is cognizant of the dangers of taking an extreme position. One extreme—particularly tempting to us—is to favor repetition of past patterns of the now developed countries, patterns that, under the markedly different conditions of the presently underdeveloped countries, are almost bound to put a strain on the existing social and economic institutions and eventuate in revolutionary explosions and authoritarian regimes. There is danger in simple analogies; in arguing that because an unequal income distribution in Western Europe in the past led to accumulation of savings and financing of basic capital formation, the preservation or accentuation of present income inequalities in the underdeveloped countries is necessary to secure the

same result. Even disregarding the implications for the lower-income groups, we may find that in at least some of these countries today the consumption propensities of upper-income groups are far higher and savings propensities far lower than were those of the more puritanical upper-income groups of the presently developed countries. Because they may have proved favorable in the past, it is dangerous to argue that completely free markets, lack of penalties implicit in progressive taxation, and the like are indispensable for the economic growth of the now underdeveloped countries. Under present conditions the results may be quite the opposite—withdrawal of accumulated assets to relatively "safe" channels, either by flight abroad or into real estate; and the inability of governments to serve as basic agents in the kind of capital formation that is indispensable to economic growth. It is dangerous to argue that, because in the past foreign investment provided capital resources to spark satisfactory economic growth in some of the smaller European countries or in Europe's descendants across the seas, similar effects can be expected today if only the underdeveloped countries can be convinced of the need of a "favorable climate." Yet, it is equally dangerous to take the opposite position and claim that the present problems are entirely new and that we must devise solutions that are the product of imagination unrestrained by knowledge of the past, and therefore full of romantic violence. What we need, and I am afraid it is but a truism, is a clear perception of past trends and of conditions under which they occurred, as well as knowledge of the conditions that characterize the underdeveloped countries today. With this as a beginning, we can then attempt to translate the elements of a properly understood past into the conditions of an adequately understood present.

V. *Concluding Remarks*

In concluding this paper, I am acutely conscious of the meagerness of reliable information presented. The paper is perhaps 5 per cent empirical information and 95 per cent speculation, some of it possibly tainted by wishful thinking. The excuse for building an elaborate structure on such a shaky foundation is a deep interest in the subject and a wish to share it with members of the Association. The formal and no less genuine excuse is that the subject is central to much of economic analysis and thinking; that our knowledge of it is inadequate; that a more cogent view of the whole field may help channel our interests and work in intellectually profitable directions; that speculation is an effective way of presenting a broad view of the field; and that so long as it is recognized as a collection of hunches calling for further investigation rather than a set of fully tested conclusions, little harm and much good may result.

Let me add two final comments. The first bears upon the importance of additional knowledge and a better view of the secular structure of personal income distribution. Since this distribution is a focal point at which the functioning of the economic system impinges upon the human beings who are the living members of society and for whom and through whom the society operates, it is an important datum for understanding the reactions and behavior patterns of human beings as producers, consumers, and savers. It follows that better knowledge and comprehension of the subject are indispensable, not only in and of itself but also as a step in learning more about the functioning of society—in both the long and short run. Without better knowledge of the trends in secular income structure and of the factors that determine them, our understanding of the whole process of economic growth is limited; and any insight we may derive from observing changes in countrywide aggregates over time will be defective if these changes are not translated into movements of shares of the various income groups.

But more than that, such knowledge will contribute to a better evaluation of past and present theorizing on the subject of economic growth. It was pointed out in the opening lines of this paper that the field is distinguished by looseness of concepts, extreme scarcity of relevant data, and, particularly, pressures of strongly held opinions. The distribution of national product among the various groups is a subject of acute interest to many and is discussed at length in any half-articulate society. When empirical data are scanty, as they are in this field, the natural tendency in such discussion is to generalize from what little experience is available—most often the short stretch of historical experience within the horizon of the interested scholar, which is brought to bear upon the particular policy problems in the forefront. It has repeatedly been observed that the grand dynamic economics of the classical school of the late 18th and early 19th centuries was a generalization, the main empirical contents of which were the observed developments during half to three quarters of a century in England, the mother country of that school; and that it bore many of the limitations which the brevity and exceptional character of that period and that place naturally imposed upon the theoretical structure. It is also possible that much of Marxian economics may be an overgeneralization of imperfectly understood trends in England during the first half of the 19th century when income inequality may have widened; and that extrapolations of these trends (*e.g.*, increasing misery of the working classes, polarization of society, etc.) proved wrong because due regard was not given to the possible effects upon the economic and social structure of technological changes, extension of the economic system to much of the then unoccupied world, and the very structure of human wants. Wider empirical foundations,

observation of a greater variety of historical experience, and a recognition that any body of generalizations tends to reflect some limited stretch of historical experience must force us to evaluate any theory—past or present—in terms of its empirical contents and the consequent limits of its applicability—a precept which naturally should also be applied to the oversimplified generalizations contained in the present paper.

My final comment relates to the directions in which further exploration of the subject is likely to lead us. Even in this simple initial sketch, findings in the field of demography were used and references to political aspects of social life were made. Uncomfortable as are such ventures into unfamiliar and perhaps treacherous fields, they can not and should not be avoided. If we are to deal adequately with processes of economic growth, processes of long-term change in which the very technological, demographic, and social frameworks are also changing—and in ways that decidedly affect the operation of economic forces proper—it is inevitable that we venture into fields beyond those recognized in recent decades as the province of economics proper. For the study of the economic growth of nations, it is imperative that we become more familiar with findings in those related social disciplines that can help us understand population growth patterns, the nature and forces in technological change, the factors that determine the characteristics and trends in political institutions, and generally patterns of behavior of human beings—partly as a biological species, partly as social animals. Effective work in this field necessarily calls for a shift from market economics to political and social economy.

THE CELLOPHANE CASE AND THE NEW COMPETITION

By GEORGE W. STOCKING AND WILLARD F. MUELLER*

On December 13, 1947 the Department of Justice instituted civil proceedings against E. I. du Pont de Nemours & Company, charging du Pont with having monopolized, attempted to monopolize, and conspired to monopolize the manufacture and sale of cellophane and cellulose caps and bands in the United States in violation of section 2 of the Sherman Act. Almost precisely six years later Paul Leahy, Chief Judge of the United States District Court for the District of Delaware, rendered a decision in the matter.[1] He pointed out that the charge against du Pont of having monopolized cellophane involved two questions: "1. does du Pont possess monopoly powers; and 2., if so has it achieved such powers by 'monopolizing' within the meaning of the Act and under *United States* v. *Aluminum Company of America* [?]" He concluded that "unless the first is decided against defendant, the second is not reached."[2] Judge Leahy did not need to reach the second question for he found the defendant not guilty. In doing so he concluded that "[f]acts, in large part uncontested, demonstrate du Pont cellophane is sold under such intense competitive conditions acquistion of market control or monopoly power is a practical impossibility."[3] In reaching this conclusion Judge Leahy reviewed at length evidence introduced by the defendant to show that du Pont behaved like a competitor, not like a monopolist. The court found that du Pont conducted research to improve manufacturing efficiency, to reduce cost of production, and to improve the quality and develop new types of cellophane. It promoted the development and use of packaging machinery that could handle both cellophane and other flexible wrapping materials. In doing so it not only helped to increase cellophane sales but stimulated improvement

[1] *United States* v. *E I du Pont de Nemours & Co.*, 118 F. Supp 41 (D. Del. 1953). This study is based largely on the testimony and exhibits in this case, but it does not consider cellulose caps and bands. Du Pont discontinued making caps before the government filed its complaint, and the district court, as with cellophane, found no monopolizing of bands. The Supreme Court has indicated that it will review this decision. References to the government's exhibits will be designated as GX, to the defendant's exhibits as DX, and to the transcript of testimony as T.

[3] *Ibid.*, pp. 197-98.

in rival flexible wrapping materials. It supplied customers with technical services to help them solve problems created by the use of cellophane. It developed over fifty types of cellophane tailored to meet the special wrapping needs of particular products. It studied the buying habits of the public. It conducted market studies to determine the effect on sales of packaging a product in cellophane. It promoted sales by educating potential cellophane users to the sales appeal of a transparent wrapping material. It reduced prices to get into new and broader markets. The court found that in response to price and quality changes buyers at times shifted from cellophane to competing products and back again. The court concluded that "[t]he record reflects not the dead hand of monopoly but rapidly declining prices, expanding production, intense competition stimulated by creative research, the development of new products and uses and other benefits of a free economy."[4]

This conclusion, based as it is on 7500 pages of testimony and 7000 exhibits, cannot easily be dismissed. Many economists relying on the logic of the "new competition" will find in it support for their theories. One has already pronounced Judge Leahy's opinion as a victory for our profession.

Such an optimistic conclusion so lightly reached by an economist and such high praise so extravagantly given by a judge warrant, first, a brief statement of the criteria by which economists can determine the existence of monopoly and, second, an application of the relevant criteria to du Pont's cellophane operations in an effort to answer the question, has du Pont had monopoly power in making and selling cellophane?

Detecting monopoly is simpler than measuring it.[5] While economists recognize that few if any industrial markets are free entirely from the influence of monopoly, by studying the structure and behavior of markets they can generally isolate characteristics which taken together will permit them to classify markets as effectively competitive or noncompetitive. In trying to classify du Pont's market for cellophane, we shall rely primarily on three criteria: (1) What role has business strategy played in du Pont's production and sales policies? (2) Is cellophane sufficiently differentiated from rival products to have a distinct market, or is its market that of all flexible wrapping materials? (3) Do the trend and level of its earnings reflect monopoly power or competition?[6]

[4] *Ibid*, p. 233.

[5] Fritz Machlup is probably correct in concluding that "so many different elements enter into what is called a monopolistic position and so complex are their combined effects that a measurement of 'the' degree of monopoly is even conceptually impossible." *The Political Economy of Monopoly* (Baltimore, 1952), p. 527.

[6] Clair Wilcox uses the following criteria in classifying markets in his TNEC study,

I. *Business Strategy as Evidence of Monopoly*

Economists have said a good deal about the role which strategy plays among oligopolists jockeying for market position. They have said less about the significance of business strategy as a basis for classifying an industry as monopolistic or workably competitive. We believe it is an important criterion. Purely competitive markets do not generally confront buyers and sellers in the business world. Frequently sellers are few, products are differentiated, knowledge is imperfect, obstacles to the movement of factors exist. Business firms from time to time make deliberate adjustments in both their price and production policies; they resort to strategy to improve their lot. Strategy may be directed to other than price and production policies. Business executives are constantly alert for any business advantage that will make their market position more secure or isolate them from the impact of competitive forces. They seek control of the sources of the best raw materials and the richest natural resources. They try to improve their products and processes or to discover and develop new and better ones. They try to protect their accumulated know-how as business secrets or, where they can, to obtain patents that legalize monopoly.

Economists recognize these practices as manifestations of business rivalry, as aspects of the sort of competition that characterizes modern industrial markets. Business rivalry is itself a symptom of the absence of pure competition. Farmers who, lacking government aid, sell in competitive markets do not regard each other as business rivals but as neighbors. But even when businessmen forego active price competition, they generally do not abandon all rivalry. Correctly, economists have concluded that this rivalry may protect the public interest. It leads to technological innovation and to economic progress. Although economists recognize that business strategy may lead to monopoly, some economists believe that in a dynamic capitalistic society monopoly is inevitably short-lived. It is continually being undermined by the rivalry of other

---

Competition and Monopoly in American Industry (1940) (1) the number of producers and the extent of industrial concentration, (2) uniformity of price quotations, (3) degree of price flexibility, (4) volume of production and extent of utilization of capacity, (5) rate of profit, and (6) rate of business mortality. Alone no one of these is a satisfactory index, and together they may be misleading unless perchance there is a consistency among the several indexes. We place considerable emphasis on two factors not included in Wilcox's list, business strategy and product differentiation, and we consider only incidentally if at all most of the factors on which Wilcox relied. Applying Wilcox's criteria to our conception of the cellophane market, we find that producers are few, concentration is high, profits are high, turnover of producing units is low, business mortality is low. These criteria suggest monopoly power. On the other hand, cellophane prices have been flexible and surplus capacity has been negligible. These characteristics suggest competition. Whether or not the factors we have chosen are adequate to answer the question we have raised we leave to the reader.

firms. The better product, the better process of today gives way to the better product, the better process of tomorrow. Only the imperfections and mortality of monopoly make it tolerable. Businessmen striving for monopoly promote the public welfare by failing to achieve their goal. Where they achieve it, either by independent business strategy or by collusive action, the public interest may not be served.

With these principles in mind, let us examine du Pont's strategy in developing the cellophane business in the United States. In doing this we do not mean to suggest that its strategy was immoral or unlawful. As Knauth has so well said:

> The contracts and arrangements which businessmen make from day to day seem to them wise, prudent, sound, and inherent in the nature of modern business. When their practices receive legislative interpretation and are denounced as monopolistic, they are puzzled. What has hitherto been deemed eminently proper and ethical now subjects them to unexpected criticism and opprobrium.[7]

No opprobrium is intended in this analysis.

Du Pont became acquainted with cellophane through its production of artificial silk. In 1920 it had entered into a contract with the Comptoir des Textiles Artificiels, a French corporation, which through its affiliates was then an important manufacturer of rayon in France, Switzerland, Belgium, and Italy, for the joint operation of an American rayon company using the viscose process. The viscose solution for making rayon was practically identical with that used in making cellophane.[8] The Comptoir had made about 970,000 pounds of cellophane in 1922, nearly 40 per cent of which it sold in the American market as a transparent wrapping material. Aware of the affinity of rayon and cellophane processes and impressed by the prospects of large cellophane sales in the American market, du Pont in 1923 signed an option contract with Arena Trading Corporation,[9] a Delaware corporation which was acting for itself and its associates, including La Cellophane, Société Anonyme, the Comptoir's affiliate which made cellophane. Under the option Arena provided du Pont with all relevant economic and technical information to enable it to decide within four months whether it wished to make and sell cellophane in North and Central America through a corporation jointly owned by it and La Cellophane. If du Pont decided affirmatively, Arena agreed to transfer to the new corporation its technical knowledge, patent rights, trade marks, and good will and the ex-

[9] Agreement of January 6, 1923, GX 1458, pp. 5999-6009.

clusive right to make and sell cellophane in the North and Central American markets. This arrangement apparently contemplated the new corporation's becoming the sole producer of cellophane in these markets. At that time only the French Comptoir through its affiliates made cellophane any place in the world.

On June 9, 1923 du Pont entered into an organizational agreement providing for the transfer to the new company, Du Pont Cellophane Company, Inc., of "an unqualified, unrestricted and exclusive right to use all and every process now owned" by Arena "or which may hereafter be acquired by it . . . in connection with the manufacture of cellophane . . ."[10]

Before entering into this agreement du Pont had made an intensive study of the market possibilities of cellophane and of its production problems and decided that Arena could not deliver all the protection from competition that it had promised. About the patents du Pont's development department had said: "[T]he patent protection at present is exceedingly inadequate not to say worthless, and the future patent protection is problematical because it is based on applications for patents, the issuance of which may not be determined for a matter of two years or more."[11] The development department had concluded that it was "by no means certain that the American Cellophane Company could *maintain* a monopoly on the strength of either present or prospective patents."[12] Du Pont accordingly insisted on a provision in the organizational agreement that should the patent protection prove inadequate, Arena was to forfeit ten thousand shares of common stock in the new company.[13]

Du Pont apparently recognized that La Cellophane's trade secrets promised a protection from competition that the patents did not, and that as the first domestic producer of a differentiated if not unique product[14] it could for some time at any rate anticipate monopoly revenue in making and selling cellophane. It calculated that with an investment of $2,000,000, at current domestic prices for imported cellophane it

[10] GX 1001, p. 992. The agreement specifically excluded processes which might subsequently be acquired by Arena from third parties, but it gave du Pont an option to purchase such rights for the North and Central American markets. Although Arena did not guarantee the validity of the patents to be licensed (*ibid.*, p. 989), it specifically promised to give the new company "the exclusive right to manufacture cellophane in North and Central America to be used for any purpose whatsoever." *Ibid.*, p. 993. Arena and Du Pont Cellophane signed their license agreement December 26, 1923. GX 1002, pp. 998-1001.

[14] Du Pont's development department concluded that glassine, sheet gelatin, and tin foil, cellophane's closest rival products, offered no serious competition because of price or quality differences. GX 392, pp. 5437-38.

could earn $631,832, an annual rate of 31.6 per cent.[15] This it regarded as sufficiently attractive to justify the venture.

Du Pont the Sole Domestic Producer

Du Pont became the sole domestic producer of cellophane and thereby a monopolist in its sale. The Department of Justice contended that it was an unlawful monopoly from the outset,[16] but the district court decided otherwise. Whether lawful or not, du Pont was a monopolist in producing cellophane, and it anticipated and in fact earned monopoly profits from the outset.

This is a characteristic of any successful innovation. As Knight has pointed out,

> There is . . . no clear distinction in practice between profit and monopoly gain. . . . New products . . . must also yield enough temporary monopoly revenue to make such activities attractive.[17]

But as Knight has also pointed out, we must distinquish between justifiable monopoly revenue—returns to the innovator—and what Knight calls monopoly gains. Monopoly gains according to Knight are monopoly revenues that are "too large or last too long." What is too long or too large Knight does not say, but he clearly implies that the procedure by which they are made large and perpetuated may convert justifiable monopoly revenue into socially unjustifiable monopoly gains.

Having achieved at the outset a monopoly in producing and selling cellophane in the American market, du Pont took steps to protect its position.

One of its first strategic moves was to obtain an increase in the tariff. This became urgent in 1925, when Société Industrielle de la Cellulose (SIDAC) completed a cellophane plant in Belgium and began exporting cellophane to the American market at cut-rate prices. Du Pont first considered a patent infringement suit against Birn & Wachenheim, SIDAC's American distributors, but fearful that it would lose such a suit decided against it and in favor of a try for higher duties.[18] Its first step

[15] *Ibid.*, p. 5451.

[17] F. H. Knight, "An Appraisal of Economic Change—Discussion," Proceedings of the American Economic Association, *Am. Econ. Rev.*, May 1954, XLIV, 65.

[18] About the suit Dr. Sparre of du Pont wrote W. C. Spruance, du Pont vice president, on August 3, 1925: "My belief is that it would cost a whole lot of money and that we would lose in the end, that is if the other side would be willing to fight." GX 1069, p. 1153. About du Pont's effort to get higher duties on cellophane, L. A. Yerkes, president of Du Pont Cellophane, had written Spruance on July 25: "In order that you shall be entirely familiar with the Cellophane status, I want to let you know that we are endeavoring to have the duty on Cellophane raised from 25% to 45%, and Curie, Lane

in getting the tariff raised was to request the United States Commissioner of Customs to reclassify cellophane as a "cellulose compound" instead of as a "gelatin compound." When the Commissioner refused, du Pont appealed to the United States Customs Court. Its appeal was successful; the court ordered a reclassification and on February 24, 1929 the duty increased from 25 to 60 per cent ad valorem.[19] Apparently this was enough to prevent price cutting by importers. At any rate du Pont's quarterly competitive report for the second quarter of 1929 stated:

> The present tariff rate (.40 per pound) as fixed by the United States Customs Court, has increased the cost of importing Transparent Cellulose Sheeting to such an extent that the competitors are adhering more rigidly to their published price list. Their selling policy in the past has been to obtain preference with the manufacturer by offering special price concessions.[20]

Du Pont won the field so completely from imported cellophane that its cellophane sales for 1929 represented 91.6 per cent of the total business in the United States,[21] whereas importers had had 21 per cent in 1927 and 24 per cent in 1928.[22] The Tariff Act of 1930 fixed the duty on imported cellophane at 45 per cent ad valorem,[23] and cellophane imports were never again significant. In no year between 1930 and 1947 did they amount to 1 per cent of cellophane consumption in the United States.[24]

Division of World Markets

La Cellophane's plan to develop the American market through a single company jointly owned by it and a domestic firm was not unique. Before transferring to Du Pont Cellophane Company, Inc., its rights to the American market. La Cellophane had made a similar agreement

with Kalle & Company (hereinafter Kalle) covering the German market. Ultimately Kalle obtained exclusive rights to La Cellophane's process and patents for the manufacture and sale of cellophane in Germany, Austria, Hungary, Czechoslovakia, Yugoslavia, Poland, Russia, Romania, China, Denmark, Sweden, Norway, and Finland.[25]

Although La Cellophane had agreed to furnish du Pont with such technological information and patent rights as it might later acquire from its other licensees, du Pont sought to fortify its market position through a direct agreement with Kalle.[26] On May 7, 1929 both parties agreed to exchange free of charge except for patent fees all patent rights and technical data covering cellophane that they then had or might later get.[27] This agreement did not specifically recognize a division of markets, but on October 30, 1929, C. M. Albright, Du Pont Cellophane vice president, listed for the Buffalo office the countries to which Kalle had exclusive rights. About the agreement Albright wrote: "The agreement, for obvious reasons, does not include the territorial limits, and it is suggested that this letter be attached to the copy of agreement for our future guidance."[28] By the summer of 1930 du Pont had patents on its moistureproof cellophane in the United States and possessions, Belgium, France, and Italy and had applications pending in Great Britain, Canada, Japan, the European countries in Kalle's exclusive territory, and eight South American countries.[29] Du Pont assigned its moistureproof patent rights in the countries in Kalle's territory to Kalle or gave it implied licenses under which Kalle took out patents in its own name.[30]

[25] Letter of October 30, 1929 from C. M. Albright, Du Pont Cellophane vice president, to the Buffalo office, GX 1091, p 1195

[26] As early as September 1925, J. E. Crane, du Pont's European manager, had written H. G. Haskell, du Pont vice president, of talks with Dr Duttenhofer of Kalle & Company on the desirability of cooperation between du Pont and Kalle Crane wrote "Dr Duttenhofer stated that as we were to cooperate in other matters it would be a pity to compete in artificial silk and cellophane" GX 1393, p 1800

[27] GX 1687, pp 1183-86 Perhaps another reason for du Pont's wishing to deal directly with Kalle is that on April 1, 1929 Du Pont Cellophane became du Pont's wholly owned subsidiary by an exchange of stock Du Pont organized a new corporation, also named Du Pont Cellophane Co., Inc., La Cellophane to sit on its board as long as du Pont considered this in the new company's best interest The 1923 agreements remained in force Agreement of March 18, 1929 between du Pont and La Cellophane, GX 1003, p 1005 On July 1, 1936, du Pont dissolved Du Pont Cellophane Co., Inc., and replaced it with a cellophane division in its rayon department Memorandum dated February 17, 1944, on the history of du Pont cellophane, prepared in du Pont's cellophane division, GX 1, p. 8.

[28] GX 1091, p. 1195.

[29] Memorandum dated August 26, 1930, from Du Pont Cellophane's cellophane department to W. S. Carpenter, Jr., chairman of its board of directors, GX 2469, p. 3164.

[30] Du Pont Cellophane memorandum dated March 17, 1933, GX 1098, p 1205; letter to Kalle dated March 20, 1933, GX 1099, p 1206; memorandum dated April 27, 1934,

Five years later du Pont entered a technical exchange and license agreement with British Cellophane Limited (hereinafter BCL), a La Cellophane licensee, which specifically delineated the territories within which each party would operate.[31] Under this agreement du Pont was to assign its British patents on moistureproof cellophane to BCL. Du Pont also assigned its French patents on moistureproof cellophane to La Cellophane[32] and its Canadian patents to Canadian Industries Limited.[33]

Meanwhile all the world's leading cellophane producers except du Pont had tried to establish an international cartel to assign territories and fix quotas among themselves. Du Pont representatives attended the first day of the cartel conferences in Paris February 11-12, 1930 as "guests and observers" but did not sign the "official report" (agreement).[34] The district court found that they were not authorized to make commitments for du Pont and made none. Nevertheless the agreement recognized the North American market as belonging to du Pont and Sylvania.[35] It did not cover moistureproof or photographic cellophane. SIDAC and La Cellophane agreed to study the possibility of pooling their patents but with the understanding that this would not apply to du Pont patents.[36]

In 1934 du Pont relied on the 1930 cartel agreement in asserting its right to the West Indies as against BCL, to which La Cellophane had granted a license and with which du Pont was then negotiating its technical agreement. In a December 13, 1934 letter to La Cellophane[37] du Pont referred to the minutes of the February 11-12, 1930 meetings of cellophane producers and quoted La Cellophane's letter of April 1, 1932[38] describing the cartel's division of the world and containing the phrases, "Cuba being situated north of the Panama Canal, belonging

[35] Sylvania Industrial Corporation's entry into the American market is described in the following subsection.

[36] The court was not impressed by the "official report" of the cartel agreement. It stated: "Failure to prove any effect from it, this cartel aspect of the case raises a straight issue of fact. Du Pont did not make such an agreement." 118 F. Supp. at 221. Moreover, the court found that the actual conduct of the producers implicated in the agreement was inconsistent with the existence of a cartel. In the court's inimitable language, "Intricate theories of a conspiratorial network is cast aside." *Loc. cit.*

[37] GX 1034, pp. 1064-65.

[38] GX 1022, p. 1044.

thus to your territory." By May 21, 1935 the du Pont-BCL agreement[39] had been signed and du Pont and La Cellophane had agreed that du Pont's territory included the West Indies except the possessions of European powers.[40]

The cartel's course was not an easy one. World depression and the pressure of totalitarian governments for foreign exchange turned members' eyes toward South American markets, and even with agreements and quotas South American prices were unstable. Du Pont's sales there under its 1930 agreement with La Cellophane (discussed in the following subsection) were particularly disturbing to cartel members.[41] On September 6, 1938 La Cellophane wrote du Pont that "it is apparently impossible to bring about a price accord for South America in our Convention."[42] The second world war weakened still further agreements to divide markets. Du Pont's agreements with Kalle and BCL were to run twenty years, subject to renewal, but in 1940 du Pont disavowed all formal territorial limitations, not only with these companies but with Canadian Industries Limited and La Cellophane as well, "in the light of legal developments in this country."[43]

SIDAC Competes with La Cellophane and with du Pont

Although La Cellophane had promised du Pont a monopoly in making and selling cellophane in the United States, it could not fulfill the promise. As du Pont feared, neither its patents nor its know-how was sufficient to protect it from competition. In 1925 two former employees of La Cellophane, using La Cellophane's trade secrets, helped establish

[39] Agreement of May 3, 1935, GX 1109, pp. 1229-34

[40] Memorandum dated May 21, 1935, "to be attached to original contract between E. I. du Pont de Nemours & Co. and Arena Trading Corporation of June 9, 1923," GX 1040, pp. 1075-76.

[41] Du Pont's 1930 agreement with La Cellophane gave du Pont half of whatever rights La Cellophane got in South America and Japan Early in 1932 du Pont wrote La Cellophane that "we have made our prices in South America on plain Cellophane to correspond with yours" (letter dated January 29, 1932, GX 1112, p. 1248), and it tried to find out what quotas for South America La Cellophane and the other producers had agreed on; but it became dissatisfied with the operation of the agreement and on June 2, 1932 informed La Cellophane that henceforth du Pont would "consider ourselves free to pursue our own policy of sales in South America, Japan and China." GX 1023, p. 1045. La Cellophane did not take this declaration of independence too seriously and continued to point out that du Pont sold more than La Cellophane did in South America and Japan. On December 27, 1934 du Pont, although reiterating its stand taken in 1932, expressed willingness to exchange figures on its sales in those markets for La Cellophane's and those "of the other members." GX 1037, p 1070

SIDAC, which began to sell in the rich American market.[44] It made its first sales through Birn & Wachenheim, who had handled La Cellophane's business in the United States before the organization of Du Pont Cellophane. In 1929 SIDAC established an American subsidiary, the Sylvania Industrial Corporation of America, and quit exporting cellophane to the United States.[45] By this time it had subsidiaries in England and Italy and competed in La Cellophane's export markets. La Cellophane sued SIDAC for patent infringement and in settlement accepted a stock interest in SIDAC; thus indirectly it became through Sylvania du Pont's competitor in the American market, in violation of its 1923 agreements with du Pont.

Negotiations over this matter were prolonged. Du Pont conceived its problem to be how to "accept reparations and at the same time protect its future position without contravening American statutes."[46] In lieu of reparations La Cellophane lifted the 1923 restriction limiting du Pont to the North and Central American markets. La Cellophane granted it equal rights with itself in Japan and South America.[47] La Cellophane also agreed to keep technical information, patents, and other data which it received from du Pont from going directly or indirectly to SIDAC or Sylvania.

Du Pont Seeks Patent Protection

When du Pont obtained its option to participate jointly with La Cellophane in developing the American market, it had not investigated the validity of La Cellophane's patent claims. The terms of the option had been "predicated on the practical absence of serious competition on the part of other manufacturers either in this country or other countries."[48] Shortly after its organization Du Pont Cellophane launched a research program designed to strengthen its market position by improving cellophane. One of its chief defects was its permeability to moisture. Du Pont promptly attacked this problem and by 1927 had developed a moistureproofing process and had applied for patents. Its basic patent

covering moistureproof cellophane, Church and Prindle patent No. 1,737,187 issued in 1929, was a product patent broad in scope and extensive in claims.[49] J. E. Hatt, general manager of Du Pont Cellophane's cellophane department, in summarizing du Pont's moistureproof cellophane patent situation in 1930 recognized its vulnerability and indicated that du Pont had taken steps to bulwark it. He described patent applications that du Pont had filed and quoted patent counsel's opinion that they promised "important and substantial additional protection."[50] Between 1930 and 1934 Du Pont Cellophane authorized a research project further to bolster its patent position. In reporting on the success of this project in 1934 President Yerkes said:

> This work was undertaken as a defensive program in connection with protecting broadly by patents the field of moistureproofing agents other than waxes which was the only class of material disclosed in our original Cellophane moistureproofing patents.
>
> The investigations on this subject did, in fact, lead to the discovery of a number of classes of materials which could serve equally well for moistureproofing agents . . . Each of these classes has been made the subject of a patent . . . Altogether, 13 patent applications are being written as a result of the work done under this project, all in view of strengthening our Moistureproof Cellophane patent situation.[51]

These steps proved adequate to forestall other domestic competition[52]

[49] A problem arising during the second world war when the government needed more moistureproof laminated products than du Pont could supply directly, reflects the breadth of the patent claims. Hines of du Pont posed the problem in this way: "What is the best procedure to give the Government these laminated products necessary to win the war and, having decided on that, what can be done to preserve du Pont's position in a postwar economy?" Recognizing that the government's interest might best be served by allowing converters to make them, du Pont feared that the converters might "at the end of the war, be possessed of a great deal of information with respect to the preparation of moistureproofing compositions and the technique of moistureproofing film with them and would be disposed to continue in such a business on a peace-time basis to the detriment of the Company's interests." Memorandum dated January 26, 1942 from du Pont's patent service to du Pont's cellophane research section, GX 2497, pp 3255 57.

[50] Memorandum of August 26, 1930, GX 2469, p. 3160

[51] December 1933 report to Du Pont Cellophane's board of directors, January 22, 1934, GX 488, p. 6478 Du Pont spent $19,503 on this research project This compares with an expenditure of only between $5,000 and $10,000 authorized in October 1924 to hire a single chemist to develop the original moistureproofing process DX 393 and DX 394. Total expenditures for "technical activities expenses," which included all types of technical work designed to improve cellophane production and processes, came to only $32,048 during 1925 and 1926. DX 387.

[52] Du Pont's strong patent position may not have been wholly responsible for the reluctance of other domestic companies to produce cellophane. Apparently Union Carbide & Carbon Corporation in the 1930's considered entering the cellophane field It purchased rights to a process for making a transparent wrapping material similar to cellophane Lammot du Pont in a letter of December 2, 1931 to L. A. Yerkes, president of Du Pont Cellophane, stated that in the course of an hour's conversation on this topic with Messrs. Jesse Ricks and Barrett of Union Carbide & Carbon "[t]hey assured me re-

and to bring Sylvania Industrial Corporation to terms when it invaded the American market.

Sylvania Reaches Accord with du Pont

Sylvania completed its Virginia plant for making cellophane in 1930. Apparently its early experimental research to develop a moistureproof cellophane rested, as did du Pont's, on the use of a nitrocellulose base to which gum, wax, and plasticizer were added. When du Pont's Charch and Prindle patent covering moistureproof cellophane was issued, du Pont advised Sylvania informally of its claims and Sylvania after considering them "felt obliged to discard the work they had done up to that time, and approach the subject from a new angle."[53] Their new angle substituted a vinyl resin base for the nitrocellulose base. Du Pont, regarding this as an infringement, advised Dr. Wallach, Sylvania's president, that "we would be obliged to enforce our patent"[54] and eventually filed an infringement suit against Sylvania.[55] In the antitrust proceedings against du Pont the government contended that the "entire infringement suit was nothing more than a harassing action designed to coerce Sylvania into entering a highly restrictive agreement."[56] The district court in finding for du Pont rejected this contention.[57] Since the court has spoken, we do not express judgment on this

---

peatedly they did not wish to rush into anything, most of all a competitive situation with du Pont. Their whole tone was most agreeable . . . In the course of the conversation, various efforts at co-operation between Carbide and du Pont were referred to, and in every case assurances of their desire to work together, given." GX 4381, p. 4300.

[55] The bill of complaint in *Du Pont Cellophane Company* v. *Sylvania Industrial Corporation* appears in the record of the Cellophane case as GX 2479, pp. 3183-90, and Sylvania's answer as GX 2480, pp. 3191-99.

[56] Statement to the court by J. L. Minicus, counsel for the government, T. 2472.

[57] Judge Leahy said: "Neither party dictated the terms of the license agreement by which the suit was settled" 118 F. Supp. at 151. He based this finding on testimony by L. A. Yerkes, president of Du Pont Cellophane. Although Judge Leahy had said that if he found that du Pont did not possess monopoly power it would be unnecessary for him to pass on whether it had monopolized cellophane under section 2 of the Sherman Act and the principles of *United States* v. *Aluminum Co. of America*, 148 F. 2d 416 (2d Cir. 1945), he nevertheless made a decision on that charge also. He ruled that du Pont's licensing and technology exchange agreements with La Cellophane did not unreasonably restrain trade and that their territorial limitations were ancillary to the acquisition of trade secrets. 118 F. Supp. at 219. He ruled that the circumstances under which du Pont acquired its patents failed to show that the "acquisitions affected its ability to exclude competition" (*ibid.*, p. 212), and that du Pont placed only "lawful and reasonable limitations on use" in its licenses (*ibid.*, p. 211). In any event, he ruled, du Pont had a lawful monopoly in its moistureproof cellophane patent. He said: "Evidence does not disclose combining of competing or independent process patents or efforts to control unpatented products" (*ibid.*, p. 214).

issue. But we wish to review briefly evidence that throws some light on du Pont's strategy.

The record indicates that (1) du Pont in negotiating for reparations following SIDAC's entry into the American market considered and rejected a proposal that it grant Sylvania a license which would restrict its output; (2) after warning Sylvania that it would defend its patents and learning that Sylvania challenged their validity, du Pont postponed action while entrenching its patent position;[58] (3) although professing confidence in its ability to establish its patents' validity, du Pont offered to settle the issue by granting a license limiting Sylvania's production of moistureproof cellophane to 10 per cent of the companies' combined output;[59] (4) on Sylvania's rejecting this offer du Pont formally notified Sylvania that it was infringing du Pont's moistureproofing patents and asked that it cease;[60] (5) upon its refusal to desist du Pont formally inaugurated infringement proceedings; and (6) before the proceedings were carried to completion du Pont and Sylvania settled the suit by a patent exchange and licensing agreement.[61]

Both parties no doubt thought that they stood to gain by a settlement. If Sylvania lost the suit, it would be forced to stop producing moistureproof cellophane or to produce it on such terms as du Pont might offer. If it won, anyone with adequate resources could produce cellophane, and selling cellophane would become a competitive enterprise. After a discussion with Sylvania's general counsel du Pont's patent attorney summed up Sylvania's plight as follows:

> During the conference Mr. Menken stated that in his opinion the case should be settled. He said that they were very fearful of what the result would be to their company in the event they succeeded in having the claims of the patents which are involved in the litigation held invalid. He seemed to realize the old adage that the defendant can never win. . . . If the Du Pont Cellophane Company succeeds and the patents are held to be infringed, Sylvania Industrial Corporation will be under injunction and will be obliged to stop manufacturing moistureproof wrapping tissue. On

[58] A running memorandum of developments in the du Pont-Sylvania patent controversy between July 9, 1931 and April 6, 1933, in the du Pont files, contains the following statement: "At Board meeting on 8/21/31 . . . [i]t was felt by Mr. Pritchard [du Pont's patent counsel] that actual suit against Sylvania should not be instituted until we have these claims issued in form of actual patents. . . . L A Y. [Yerkes, Du Pont Cellophane's president] still felt it would be desirable for us to have Sylvania under a license agreement if possible." GX 2478, p. 3181

[59] *Loc. cit.* On August 27, 1931 Yerkes wrote to Dr. Wallach confirming an oral offer made on or about July 9, 1931. A memorandum dated July 13, 1931 outlines the terms of the offer. GX 2483, p. 3206.

[60] GX 2478, p. 3181. The memorandum refers to a letter dated 11/19/31 which lists the patents du Pont claimed to be infringed.

[61] Agreement dated April 26, 1933, GX 2487, pp. 3212-33.

the other hand, if they succeed in having the broad claims of the patents held invalid they will throw the art open, as far as the broad claims are concerned, to anyone and therefore will have additional competition. Sylvania . . . has plenty of ready cash but are hesitant about enlarging their plant facilities pending the litigation since, if successful, they will only invite further competition.[62]

With neither side ready to test the validity of du Pont's patents, the parties compromised. The compromise constituted no threat to du Pont's dominant market position.

Under the settlement reached April 26, 1933, Du Pont Cellophane granted Sylvania a nonexclusive license (made exclusive in 1938) of du Pont's five basic patents on moistureproof cellophane and agreed to license to it any patents within their scope which du Pont might get before October 16, 1948. Sylvania agreed to grant similar rights to Du Pont Cellophane under any patents which it might get. Sylvania agreed to pay du Pont a royalty of 2 per cent of its net cellophane sales for the use of du Pont's basic patents and an additional 2 per cent if Sylvania accepted licenses under future du Pont patents representing departures from the five basic patents. But the settlement went further than a mere cross-licensing of present and future patents. It provided that Sylvania's production be restricted to a fixed percentage of total moistureproof cellophane sales, beginning with 20 per cent in 1933 and increasing by 1 per cent until it reached 29 per cent in 1942. Should Sylvania exceed its share in a given year, it agreed to pay a penalty royalty of 20 cents a pound or 30 per cent of its net cellophane sales, whichever was higher. If du Pont used any of Sylvania's patents, it agreed to a similar penalty for exceeding its basic quota. But it never used them.

Until June 1951 du Pont and Sylvania were the only producers of cellophane in the American market.[63] Between 1933 and 1945 (when they contracted for smaller royalties and abandoned penalties for exceeding their quotas), with Sylvania's output geared to du Pont's, du Pont could determine how much cellophane should come on the market. Actually the penalty provision of the agreement never operated and its deletion from the 1945 agreement produced no marked effect on Sylvania's production. The court found that "[i]ts policies as to expansion in no way changed following the termination of the 1933 agreement in 1945."[64] Although their shares varied from time to time, du Pont

[62] Letter dated August 4, 1932 from W. S. Pritchard to B. M. May, GX 2811, pp. 6073-74.

[63] In June 1951 Olin Industries, Inc., began the production of cellophane at Pisgah Forest, North Carolina. Testimony of Fred Olsen, Olin vice president, T. 6829.

[64] 118 F. Supp. at 157.

supplied about 76 per cent and Sylvania 24 per cent of the market from 1933 to 1950.[65] But gearing Sylvania's production to du Pont's must have lessened Sylvania's incentive to independent, vigorous rivalry, price or nonprice, and the record indicates that until January 1, 1947 Sylvania's quoted prices were generally identical with du Pont's.[66]

Conclusion

Du Pont's moves and countermoves to protect its domestic market were the strategy of a producer operating in a monopolistic, not a competitive, market. Its agreements with foreign producers to license patents and exchange technical data, its domestic patent program, its effort to get higher tariffs, its restrictive market agreement with Sylvania, all reflect du Pont's effort to preserve what it apparently regarded as a monopoly market. That du Pont and Sylvania (whose production was geared to du Pont's and whose quoted prices were generally identical with du Pont's) together monopolized the market for cellophane seems scarcely debatable. That du Pont acted as though in its monopoly of cellophane it had a valuable property right which it sought to exploit is equally clear. But was du Pont mistaken? Were available substitutes so similar that du Pont's monopoly of cellophane was in reality a mirage or a phantasy? Is there in fact no distinct market for cellophane, but only a larger market for flexible wrapping materials with producers so numerous that none can make monopoly profits? Let us turn to that question.

II. *Cellophane—A Differentiated Product?*

For several years du Pont was the sole domestic producer of cellophane and for a quarter of a century Sylvania and du Pont were the only producers. But buyers of flexible wrapping material need not rely solely on these two suppliers. Several hundred rivals produced flexible

[65] Data on production, 1933 to 1950, table in *United States* v. *E. I. du Pont de Nemours & Co.*, 118 F. Supp. 41, 116 (D Del. 1953) In the five years following the expiration of the 1933 agreement Sylvania's percentage of total domestic production was only 1 per cent higher than its percentage in the five years preceding the expiration of the agreement. American Viscose Corporation acquired Sylvania in 1946

[66] Du Pont and Sylvania not only quoted identical prices for their most important cellophane types, but their price changes almost always became effective on the same date. GX 549, pp 7128-66. During the postwar period of short supplies and after the government had instituted its suit against du Pont, differences in Sylvania's and du Pont's prices appeared DX 591, p 1128 Judge Leahy was impressed not by the identity of quoted prices but by the fact that Sylvania at times made discounts from its list prices which du Pont did not match. In speaking of du Pont-Sylvania competition he declared that Sylvania "has continued to expand to the full extent of its financial resources" (118 F. Supp. at 212), and that although du Pont was superior in the services rendered to customers, in technology, in price, and in the development of special types of films, competition between the two companies has "flourished" (*loc cit*).

wrapping materials, in many uses substitutes for cellophane. May not these have converted a monopolistic market into one of workable competition? Let us examine briefly the relevant theory and then the facts.

Price Theory and Product Differentiation

Although others have made important contributions to an understanding of the significance of interproduct competition, Chamberlin, the pioneer, offers a good starting point for this discussion. Chamberlin has recognized that "[a]s long as the substitutes are to any degree imperfect, he [the seller] still has a monopoly of his own product and control over its price within the limits imposed upon any monopolist—those of the demand."[67] But Chamberlin also recognized that rival products, where entry is free and differentiation not marked, could eliminate excess profits even in the "monopolized" field. Expressing his findings diagrammatically, he concluded that the sloping demand curve facing the producer of a differentiated product may become tangent to the cost curve somewhere above lowest average cost. Chamberlin regarded this as a "sort of ideal" solution. As he put it, "With fewer establishments, larger scales of production, and lower prices it would always be true that buyers would be willing to pay more than it would cost to give them a greater diversity of product; and conversely, with more producers and smaller scales of production, the higher prices they would pay would be more than such gains were worth."[68]

Chamberlin's conclusion that the entry of producers of substitute products will eliminate monopoly profits is based upon two important assumptions: (1) his uniformity assumption—"both demand and cost curves for all the 'products' are uniform throughout the group";[69] and (2) his symmetry assumption[70]—"any adjustment of price or of 'product' by a single producer spreads its influence over so many of his competitors that the impact felt by any one is negligible and does not lead him to any readjustment of his own situation."[71]

[67] E. H Chamberlin, *The Theory of Monopolistic Competition*, 5th ed. (Cambridge, Mass., 1947), p. 67.

[68] *Ibid.*, p. 94. This assumes, of course, that buyers know what they get and get what they want in buying a differentiated product This is a dubious assumption. Years ago a well-known pharmaceutical company by its advertising endeavored to create a widespread fear of halitosis "Not even your best friends will tell you." Having created a fear of halitosis, it provided a product to dissipate it, thereby rendering the buyer a service for which he was willing to pay.

[69] *Ibid.*, p 82. To simplify his exposition Chamberlin first assumes uniformity in cost and demand curves. Later he abandons this assumption in the interest of reality. In abandoning it he reaches the conclusion indicated in the text: where sufficiently effective substitutes are not offered in the market, monopoly profits result.

[70] G. J. Stigler so describes this assumption. *Five Lectures on Economic Problems* (London, 1949), p. 17.

[71] Chamberlin, *op cit*, p. 83.

If cost and demand curves are not uniform, or if the "group" of firms producing the substitute products is sufficiently small to introduce the oligopoly problem, we may expect a divergence from the above solution. As for the uniformity assumption, Chamberlin says: "[I]n so far as substitutes of such a degree of effectiveness may not be produced, the conclusions are different—demand curves will lie to the right of the point of tangency with cost curves, and profits will be correspondingly higher. This is the explanation of *all* monopoly profits, of whatever sort."[72] Thus, unless effective substitutes exist, Chamberlin argues that monopoly profits may be "scattered throughout the group."[73] If Chamberlin's symmetry assumption is not fulfilled, an oligopoly solution may be expected.[74] In either case monopoly profits result.

In applying Chamberlin's theory to the flexible packaging materials market and to cellophane's position in it, the empirical issue revolves about (1) the degree of effectiveness of substitutes, and (2) the number of rival firms. If substitutes are not effective enough to eliminate monopoly profits, it is not necessary to consider the oligopoly problem.

Clark's analysis[75] leads to similar conclusions, viz., that competition among substitutes may eliminate monopoly profits; but Clark goes further than Chamberlin in finding these results salutary. According to Clark the high cross elasticity of demand tends to flatten the monopolist's demand curve. Moreover, the monopolist's fear of potential competition may lead him to behave as though potential competition had become a reality. These two restraining forces, rival substitute products and potential competition, may yield cost-price relationships

[72] *Ibid.*, p. 111. Emphasis in original. This statement of the problem seems to make it similar to if not identical with the conventional, neoclassical conception of monopoly. Richard T. Ely for example pointed out: "The use of substitutes is consistent with monopoly, and we nearly always have them. For almost anything we can think of, there is some sort of a substitute more or less perfect, and the use of substitutes furnishes one of the limits to the power of the monopolist. In the consideration of monopoly we have to ask, what are the substitutes, and how effective are they?" *Monopolies and Trusts* (New York, 1912), pp. 35-36.

[73] Chamberlin, *op. cit.*, p. 113. By the "group" Chamberlin apparently means firms making products which although differentiated are designed for the same use, e.g., toothpaste manufacturers. In his "Monopolistic Competition Revisited," *Economica*, Nov. 1951, N.S. XVIII 352, 353, he abandons the group concept, arguing that "competition is always a matter of substitutes, and . . . substitutes are always a matter of degree." In abandoning the group concept he does not abandon the conclusion that where substitutes are similar enough and entry is free, monopoly profits will disappear and the demand curve will be tangent to the cost curve at some point above minimum cost. But he also recognizes that the "isolated" monopolist, in spite of close substitutes, may find the demand for his own product strong enough to yield him "profits in excess of the minimum."

[74] *Monopolistic Competition*, p. 102.

[75] J. M. Clark, "Toward a Concept of Workable Competition," *Am. Econ. Rev.*, June 1940, XXX, 241-56.

similar to those of pure competition. They may make imperfect competition workable.

An increasing number of economists have come to believe this. Robertson develops the idea somewhat further. In reviewing the significance of interproduct and interindustry competition he concludes that we really need not worry about monopoly for "there is probably not much of it." There is not much of it because the "old-fashioned apparatus of competition works in new ways to save us."[76]

Moreover, this new apparatus of competition once more makes relevant a theory of competition based on large numbers.

> To assess the competitive situation of a firm we must still resort to counting numbers. We cannot do away with the group, for the group exists in the real world. Yet counting only those firms which are within the "industry" tells us very little. We must do our counting by taking categories of uses for the output of an industry, considering what products of other industries directly compete within these categories.[77]

Since a monopolist's product may serve in a great variety of uses, a monopolist may find it "profitable to forego monopoly control in one use in order to push the commodity into many uses."[78] Thus monopoly serves the public by serving itself and in doing so loses its power over the market.

What Robertson has discovered for the economists, businessmen had already professed. David Lilienthal, writing about the "new competition," said:

> I am not saying that active competition between the producers of the same product is of no present consequence. It certainly is. My point is that under present-day conditions it is often the least significant form. The competition between alternative materials, or ways of satisfying human needs and desires, has become a new dimension of competition.[79]

It was on such principles that Judge Leahy relied in reaching his conclusions in the Cellophane case.

This calls for a more careful consideration of the uniqueness of cellophane, of du Pont's pricing policies in selling it, and of the rate of earnings realized in doing so. If cellophane is sufficiently differentiated from other flexible wrapping materials, its demand curve may "lie to the right of the point of tangency with its cost curve" and its producer may receive monopoly profits in making and selling it. If cellophane is

[76] R. M Robertson, "On the Changing Apparatus of Competition," Proceedings of the American Economic Association, *Am. Econ. Rev.*, May 1954, XLIV, 61.

[77] *Ibid.*, pp 53-54

[78] *Ibid.*, p. 57.

[79] D. E. Lilienthal, *Big Business: A New Era* (New York, 1953), p. 60.

a less highly differentiated product within Chamberlin's conception of the term and if entry to the manufacture of rival wrapping materials is not blocked, the maker of cellophane will be faced by a sloping demand curve; but the curve will be tangent to the cost curve at some point above lowest average cost, and the seller will not make a monopoly profit. If the differentiation is so slight and potential competition so imminent as to bring it within Clark's concept of the term, the seller's long-run demand curve will be close to the horizontal (his control over price will be slight) and prices will be close to lowest average cost. If the cellophane market conforms to Robertson's model, cellophane's differentiation will be too slight to count, monopoly profit will not exist, and its price will be competitive. To which of these models does the market for cellophane conform?

The Market for Cellophane

As a first step in answering this question we will examine briefly the flexible packaging materials market. The district court in determining whether du Pont monopolized the market for cellophane concluded that "the relevant market for determining the extent of du Pont's market control is the market for flexible packaging materials."[80] In this broad market the court found several hundred firms selling a variety of differentiated products for an even wider variety of uses. They sold either directly to packagers or to converters who prepared packaging materials for special uses. The court found that in 1949 du Pont cellophane accounted for only 17.9 per cent of the total square yardage of domestic output and imports of flexible packaging materials.[81] (Apparently this did not include kraft paper.) Such a small percentage scarcely demonstrates that du Pont had monopolized the *flexible packaging materials* market. Nor had it. But in passing judgment on the validity of the court's view that there is a single market for flexible packaging materials it may be helpful to classify the major contemporary materials according to their special qualities and major uses.

Cellophane is a thin, transparent, nonfibrous film of regenerated cellulose. It comes in two major types: plain and moistureproof. Moistureproof cellophane far outsells plain. In 1950 plain cellophane sales totalled $12,005,737; moistureproof cellophane sales, $116,660,209.[82] Because moistureproof cellophane sales are over nine times those of plain, our analysis will give primary consideration to moistureproof. Moistureproof cellophane is highly transparent, tears readily but has

[80] 118 F. Supp. at 60.

[81] *Ibid.*, p. 111.

[82] Table showing comparison of du Pont and Sylvania plain and moistureproof cellophane sales, 1924-1950, 118 F. Supp at 123.

high bursting strength, is highly impervious to moisture and gases, and is resistant to grease and oils. Heat sealable, printable, and adapted to use on wrapping machines, it makes an excellent packaging material for both display and protection of commodities.

Other flexible wrapping materials fall into four major categories: (1) opaque nonmoistureproof wrapping *paper* designed primarily for convenience and protection in handling packages; (2) moistureproof *films* of varying degrees of transparency designed primarily either to protect, or to display and protect, the products they encompass; (3) nonmoistureproof transparent *films* designed primarily to display and to some extent protect, but which obviously do a poor protecting job where exclusion or retention of moisture is important; and (4) moistureproof *materials* other than films of varying degrees of transparency (foils and paper products) designed to protect and display.

Kraft paper is the leading opaque nonmoistureproof wrapping paper. For general wrapping it has no equal. It is cheap, strong, and pliable and gives adequate protection. On a tonnage basis it easily tops all other packaging materials in total sales. But it is neither designed for nor adapted to the special uses for which cellophane was created and, as one market expert has put it, "in the true sense" does not compete with cellophane. More accurately, we think, cellophane does not compete with it. On a cost basis it cannot compete. At less than one cent per thousand square inches, kraft paper sells for less than cellophane's manufacturing cost.

The leading moistureproof *films* which might compete with cellophane include polyethylene, Saran, and Pliofilm. These are relatively latecomers in the packaging field. In some qualities they match or even excel cellophane. But we have it on the authority of du Pont market analysts that these films have offered little or no competition to cellophane in its major markets. According to du Pont's 1948 market analysis, prepared by its experts for company use in making decisions, although Saran was "superior in moisture protection, no significant commercial uses" had developed for it "due principally to its high price" and "no substantial cost reduction" was in sight.[83] In 1949 a thousand square inches of 100-gauge Saran #517 sold for about 2½ times as much as the same amount of moistureproof cellophane (see Table I). Du Pont experts found polyethylene lacking in transparency, "too limp to operate satisfactorily on wrapping machines, . . . difficult to heat seal, print and glue," with "poor surface slip and high static, and . . . permeable to volatile oils and flavorings."[84] Pliofilm, an older rival first mar-

[83] DX 595, p. 1156.

[84] *Ibid.*, pp. 1155-56. The court said of polyethylene: "Many of these deficiencies could be corrected through research, and were." 118 F. Supp at 81.

TABLE I.—COMPARISON OF AVERAGE WHOLESALE PRICES OF CELLOPHANE WITH PRICES OF OTHER FLEXIBLE PACKAGING MATERIALS IN 1949

Packaging Material	Price per 1,000 sq. in. (cents)	Per Cent of Cellophane Prices		Price per lb. (cents)	Per Cent of Cellophane Prices	
		Moistureproof	Plain		Moistureproof	Plain
Saran 100 gauge #517	6.1	265.2	290.5	99.0	207.1	221.0
Cellulose Acetate .00088"	3.3	143.5	157.1	82.0	171.5	183.0
Polyethylene .002"—18" flat width	5.4	234.8	257.1	81.0	169.4	180.8
Pliofilm 120 gauge N2	3.8	165.2	181.0	80.8	169.0	180.4
Aluminum Foil .00035"	1.8	78.3	85.7	52.2	109.2	165.2
Moistureproof Cellophane 300 MST-51	2.3	100.0	109.5	47.8	100.0	106.7
Plain Cellophane 300 PT	2.1	91.3	100.0	44.8	93.7	100.0
Vegetable Parchment 27#	1.4	60.9	66.7	22.3	46.7	49.8

Source: Prices per thousand square inches and per pound, *United States* v. *E. I. du Pont de Nemours & Company*, 118 F Supp. 41, 83 (D Del 1953). Robert Heller & Associates, management consultants, conducted the price survey for du Pont on which DX 995, the original source of these data, is based G. W. Bricker, who personally supervised the survey, testified that "each of these materials is a principal standard material of that type." T. 4497. In selecting a particular grade Bricker relied on the advice of the Bureau of Labor Statistics, American Pulp and Paper Association economists, and the individual companies from which he got his data.

keted in the mid-thirties, has a rubber base and is particularly well adapted to packaging foods preserved in liquids, a relatively narrow market. Despite its superiority in this use, its high cost (in 1949 a thousand square inches of 120-gauge Pliofilm N2 sold for about 1⅔ times as much as moistureproof cellophane) made it "an active competitor of Cellophane only in those fringe uses bordering markets that need greater moistureproof protection than Cellophane provides."[38]

[38] DX 595, p. 1153. In 1950 Goodyear developed a type satisfactory for fresh meats. 118 F. Supp. at 81.

In 1939 Pliofilm sales were only 2 per cent of cellophane sales; by 1949 they had increased to only 4.4 per cent.[86]

Cellulose acetate, a nonmoistureproof transparent *film*, is an old cellophane rival. First appearing in 1931, by 1939 its sales were only 3 per cent of cellophane's. Ten years later they were only 3.7 per cent.[87] Its chief quality disadvantage is that it is not moistureproof. It compares in quality with plain cellophane, but its 57 per cent higher price in 1949 placed it at a serious competitive disadvantage.

About these several films du Pont in its 1948 market analysis concluded:

> The principal markets for non-viscose films have been competitive with Cellophane only to a very minor degree up to this time. Some are used very little or not at all in the packaging field—others are employed principally for specialty uses where Cellophane is not well adapted—none have been successfully introduced into any of Cellophane's main markets due to their inherent shortcomings.[88]

On the superiority of cellophane as compared with other films for most of cellophane's uses, the experts apparently agreed. Olin Industries, Inc., later to become the third domestic cellophane producer, after investigation reported: "According to du Pont, Cellophane is considered the only all purpose film, and any product to be *truly competitive* with Cellophane must have the following attributes: (1) low cost, (2) transparency, (3) operate with a high efficiency on mechanical equipment, (4) print well both as to speed and appearance."[89] Olin concluded:

> There are no films currently marketed which are potentially competitive to any substantial degree in Cellophane's major markets when measured by the above attributes necessary for wide usage. Other transparent films will find their place for those low volume uses which can absorb the additional cost of the film and which necessitate certain physical properties not possessed by Cellophane.[90]

Consumer decisions confirmed the judgment of the experts. In 1949

[90] *Loc. cit.*

converters used roughly fourteen times as much cellophane as all other packaging films.[91]

Apparently cellophane has no effective rival in another segment of the flexible packaging material market, the outer wrapping of packaged cigarettes. Clear as plate glass, flexible, easily ripped open, moisture-proof, it displays and protects with such perfection that except when they can't get it cigarette makers use no other overwrap.[92] The court recognized this, noting however that makers of Pliofilm, glassine, and aluminum foil keep trying to break into this market. They have not succeeded.

The court to the contrary notwithstanding, the market in which cellophane meets the "competition" of other wrappers is narrower than the market for all flexible packaging materials. Cellophane dominates the market for cigarette overwraps, it does not compete with kraft paper for general wrapping, and in its more specialized markets the non-viscose films do not compete with cellophane except in fringe uses.

Food Packaging

In 1949, 80 per cent of du Pont's cellophane sales were for packaging food products; here cellophane encounters its most vigorous rivalry, "competing" with vegetable parchment, greaseproof paper, glassine, wax paper, and aluminum foil. Each of these wrapping materials is a differentiated bundle of qualities, competing in a wide variety of uses. Users attach a different importance to the several qualities. Many value transparency highly, a quality in which cellophane is outstanding. Some, however, regard transparency as a disadvantage. All are likely to rate moisture protection as important, but wax paper, aluminum foil, and some types of glassine are about as good as cellophane in this. Food packagers in selecting wrapping material no doubt consider carefully the unique combination of qualities represented by each of these materials. They resell the product they wrap and they are cost-conscious. Presumably they try to select the material that, quality considered, will give the greatest value. In determining values they must consider consumer response to the several materials. In any event, some buyers of packaging materials changed from one kind to another in trying to get their money's worth. Some candy makers and some bread bakers, for example, operating on narrow margins in the mid-'thirties switched from cellophane to a less costly wrapper when

[91] DX 985. This is a market analysis prepared for du Pont by Robert Heller & Associates.

[92] A shortage of cellophane in the mid-'forties forced some cigarette makers to use other materials. Brown and Williamson Tobacco Company once experimented with selling Kools and Raleigh cigarettes in a one-piece foil package 118 F. Supp. at 108.

their other production costs mounted. The court concluded from the evidence that "shifts of business between du Pont cellophane and other flexible packaging materials have been frequent, continuing and contested."[93] In no one of the more important uses for packaging foods did cellophane in 1949 supply as much as 50 per cent of the total quantity (in square inches) of wrapping materials used (see Table II).[94] Only

TABLE II.—COMPARISON BY PERCENTAGES OF TOTAL QUANTITY OF SELECTED FLEXIBLE PACKAGING MATERIALS, CLASSIFIED BY END USES*

Type of Material	Bakery Products	Candy	Snacks	Meat and Poultry	Crackers and Biscuits	Fresh Produce	Frozen Food Excluding Dairy Products
Cellophane	6.8	24.4	31.9	34.9	26.6	47.2	33.6

* Based on 1949 sales (in millions of square inches) of nineteen major converters "representing a substantial segment" of the converting industry, *United States* v. *E. I. du Pont de Nemours & Company*, 118 F Supp. 41, 113 (D.Del. 1953). G. W. Bricker of Robert Heller and Associates, management consultants employed by du Pont, testified that the above data covered two thirds of du Pont's and Sylvania's cellophane. T. 4474

in the packaging of fresh produce did cellophane sales top the list. Its percentage of total sales varied from 6.8 per cent for packaging bakery products to 47.2 per cent for fresh produce. Like du Pont's percentage of total sales of all flexible wrapping materials, these specific figures scarcely demonstrate that du Pont has monopolized the sale of flexible packaging material to food packagers.

Such facts apparently led the court to conclude that du Pont, although selling about 76 per cent of the cellophane and together with Sylvania—whose production was geared to du Pont's—selling all of it, had not monopolized the market for *all* flexible wrapping materials. No one is likely to quarrel with this finding. But in an economic sense

[93] *Ibid*., p. 91

[94] Table II is based on evidence which the court reproduced in the opinion. In less important uses not included in the court's tabulation cellophane accounted for the following percentages of total quantities of the selected flexible wrapping materials used: dry beverages, 6.4 per cent; breakfast cereals, 12 6 per cent; dry fruits and vegetables, 63.7 per cent; frozen dairy products, 1.1 per cent; flour, meal, and dry baking mixes, .5 per cent; nuts, 77.3 per cent; paste goods, 97.4 per cent; paper products, 38 per cent; and textile products, 62.3 per cent. DX 984.

a firm may have a monopoly of a differentiated product, that is, it may behave like a monopolist and enjoy the fruits of monopoly in selling it, even though it meets the rivalry of substitutes. That is the economic issue here. Is cellophane so highly differentiated that du Pont in selling it can follow an independent pricing policy, that is, is the cross elasticity of demand for cellophane so low that du Pont, while pricing it independently, can enjoy a monopoly profit in its sale? Let us examine this issue.

When du Pont first marketed cellophane, it apparently thought cellophane had unique qualities and it adopted a strategy designed to prevent competition from any other producer, in short, to protect its monopoly.[95] It also priced cellophane from the outset to yield monopoly revenue. Its long-run aim in selling cellophane was apparently that of any monopolist, viz., to maximize revenues. But the maximization of revenues over time even by a monopolist may call for a farsighted and vigorous policy in exploiting a product. Monopolists, although they can restrict output and charge relatively high prices, may not find it profitable to do so. Du Pont argued and the court concluded that the test of monopoly is the power to exclude competition and the power to raise prices. A more logical test is the power to exclude competition and the power to *control* prices. That a monopolist may find it profitable to lower prices, increase sales, and reduce costs, even though the public benefits, does not necessarily mean, as Robertson suggests, that he has relinquished monopoly power. To use monopoly power rationally is not to forego it.

President Yerkes of the Du Pont Cellophane Company, Inc., concluded as early as 1924 that to maximize earnings du Pont should reduce cellophane prices. On this issue he said:

> I am in favor of lowering the price. . . . [I] think it will undoubtedly increase sales and widen distribution. . . . Our price I think is too high based purely on manufacturing cost and too high in comparison with other wrapping papers on the market, and while we cannot approach the price of glassine or other oil papers, if we make a substantial reduction we will in some cases get somewhere near there.[96]

Walter S. Carpenter, Jr., chairman of du Pont's board of directors,

[95] If cellophane had encountered the effective competition of rival wrapping materials, du Pont would have had nothing to gain by impeding entry. That is to say, if cellophane were merely one of many substitutable products among which effective competition prevails, the price of each would be driven down to a competitive (cost-remunerative) level and it should be a matter of indifference to du Pont whether this results from rival products or from new producers of cellophane.

[96] Memorandum of some remarks made at a meeting of the board of directors, Du Pont Cellophane Company, Inc., December 11, 1924, DX 337, p. 643.

expressed a similar idea when he testified in the Cellophane case:

> . . . the purpose of reducing our price and also improving our quality was to broaden our market. . . . As a general philosophy I was always in favor of the reduction of the price as we were able to do so by the reduced costs, and I think that I consistently urged that on the management.[97]

The Yerkes-Carpenter philosophy apparently prevailed. The price of cellophane, which averaged $2.508 a pound in 1924, was reduced in every year until 1936, when it averaged 41.3 cents a pound. With minor interruptions the decline continued until cellophane sold for an average price of 38 cents a pound in 1940. Inflation accompanying the second world war reversed the trend. With few exceptions cellophane prices moved upward until 1950, when they averaged 49 cents a pound.[98] But despite the reductions moistureproof cellophane (300 MST-51, the principal type) sold at from two to seven times the price of 25# bleached glassine and from two to four and a half times the price of 30# waxed paper, its most important rivals.[99]

Du Pont's Independent Pricing Policy

On its face du Pont's pricing policy was consistent with that of a monopolist. Other evidence supports this conclusion. Had cellophane's major rival wrapping materials competed with it effectively (*i.e.*, had the cross elasticity of demand between cellophane and other wrappers been high), the prices of such wrapping materials would have moved concurrently to prevent, as Chamberlin says, "incursions by one seller, through a price cut, upon the markets of others."[100] In fact, however, while du Pont was "broadening its market" by reducing cellophane prices, the prices of other wrappers did not follow a similar pattern. Bleached glassine prices were constant from 1924 until 1933 and again from 1934 to 1938. They rose in 1939 and again in 1940. Waxed paper prices fluctuated between .5 cent and .52 cent per thousand square inches from 1933 through 1939 and in 1940 increased to .62 cent. Vegetable parchment prices declined from 1.3 cents to 1.0 cent per thousand square inches between 1924 and 1928 and thereafter fluctuated between .95 cent and 1.05 cents. Bleached greaseproof prices rose from .45 cent per thousand square inches in 1933 to about .55 cent in

[97] T. 6278-79.

[99] Defendant's Brief on the Facts and the Law, Appendix A (graph based on prices per 1,000 sq. in.), *United States v. E. I. du Pont de Nemours & Co*, 118 F. Supp. 41 (D. Del. 1953).

[100] Chamberlin, *Monopolistic Competition*, p. 90.

1940.[101] But du Pont's cellulose acetate film dropped in price from 59.3 cents a pound in 1935 to 53.6 cents in 1940,[102] and aluminum foil prices dropped from 2.45 cents to 1.65 cents per thousand square inches between 1928 and 1940. The prices of these rival products and of cellophane followed the same trend, but cellophane and cellulose acetate film sold for substantially more than aluminum foil; and it seems likely that the cross elasticity of demand between the cellulose films and aluminum foil is even less than between them and the other products compared.

Under inflation wrapping material prices have increased since 1940, but not similarly. Average cellophane prices increased by about 20 per cent between 1940 and 1949, but the prices of most other wrappers increased more rapidly: vegetable parchment, about 40 per cent; bleached glassine, 40 per cent; cellulose acetate, 50 per cent; waxed paper, 75 per cent; and bleached greaseproof, 80 per cent. The only two wrappers to increase less in price than cellophane were Pliofilm, 13 per cent, and aluminum foil, 9 per cent.[103] These price patterns indicate that cellophane continued to decrease in price relative to most other wrapping materials.

The above facts demonstrating cellophane's independence of other wrapping material prices strongly suggest that du Pont was not selling cellophane in an effectively competitive market. Either cellophane's rival products were not close enough substitutes to feel the effect of cellophane price decreases (*i.e.*, the cross elasticity of demand between cellophane and these products was low) or they were already selling at cost and could not prevent cellophane's invasion of their markets. In either event they did not constitute sufficiently close substitutes to insure effective competion.

Although du Pont lowered its cellophane prices from time to time as it re-examined its demand and cost functions, at no time did it compete with its most popular rivals on a price basis. As H. O. Ladd, director of du Pont's trade analysis division, put it:

> The main competitive materials . . . against which Cellophane competes are waxed paper, glassine, greaseproof and vegetable parchment paper, all of which are lower in price than Cellophane. We do not meet this price competition. Rather, we compete with these materials on the basis of establishing the value of our own as a factor in better packaging and cheaper distribution costs and classify as our logical markets those fields

[101] DX 994-A. These price comparisons, like those for 1949 in Table I, rest on data collected for du Pont by Robert Heller & Associates and are based on the prices of one principal standard material of each type named.

[102] GX 490, p. 6507; GX 495, p. 6665.

[103] DX 994-A.

where the properties of Cellophane in relationship to its price can do a better job for the user.[104]

But while du Pont resorted to aggressive selling, emphasizing the superiority of its product and extending its services,[105] the evidence does not indicate that at any time it carried quality competition so far as to equalize average cost and selling price. Price differences no doubt reflected at the margin the customers' evaluation of differences in quality, but the record does not indicate that they reflected differences in cost. If they had, with as many firms as are selling flexible wrapping materials, monopoly profits would have disappeared and the market would have become effectively competitive. Let us turn then to du Pont's earning record.

III. *Has Du Pont Earned Monopoly Profits?*

As du Pont reduced cellophane prices, output and sales expanded rapidly. In 1924 du Pont produced only 361,000 pounds of cellophane and sold $1,307,000 worth. A decade later it produced 39,358,000 pounds and sold $18,818,000 worth. In 1940 when cellophane sold at 38 cents a pound, its all-time low, du Pont produced 81,677,000 pounds and sold $31,049,000 worth.[106] Such increases in output and sales had called for a continuous expansion in investment. In 1925 du Pont's fixed and working capital in producing cellophane was $2,122,00. In 1934 it was $24,008,000 and a decade later $41,133,000 (see Table III).

Du Pont's production and pricing policies paid off. In 1925 it earned, before taxes (operating earnings),[107] $779,000 on its cellophane operat-

[104] GX 589, p 7530.

[105] Du Pont showed great ingenuity and aggression in developing new uses for cellophane and expanding old ones R R. Smith, assistant director of sales of du Pont's film department, testified that in 1934, when white bread regularly sold for 10 cents a loaf and its profit margin was small, he and other salesmen actually created the specialty breads industry—new varieties of bread which could be sold at a price large enough to cover the higher cost of wrapping them in cellophane. T 5704-5 In 1936 Smith studied the sales methods of door-to-door bakery salesmen and du Pont made a sales training film "which had nothing to do with packaging" (T. 5721) but showed the way to higher profits even when using cellophane. "The promotion was extremely successful." T. 5705. In 1951 du Pont had about 45 per cent of the variety bread-wrapping business T. 5721.

[106] See comparisons of du Pont and Sylvania production and sales, 1924-1950, *United States* v. *E. I. du Pont de Nemours & Co.*, 118 F. Supp. at 116, 123 (D. Del. 1953).

[107] Du Pont computes operating earnings for each operating division by deducting all of the expenses directly related to its operations from its sales. Among these expenses are production, selling, administration, and research expenditures conducted within and for the particular division. Du Pont calculates its rate of operating earnings on the basis of its working and fixed investment allocated to its cellophane operations.

Net cellophane earnings are calculated by allowing for federal income taxes, capital stock tax, franchise, state income, and foreign taxes, "B" bonus, and fundamental research by the chemicals department. Federal income and other taxes constituted the great bulk of

ing investment. In 1934 it earned $6,000,000 and in 1940, $12,000,000. Although its annual rate of earnings before taxes declined somewhat from a high of 62.4 per cent in 1928, in only two years between 1923 and 1950 inclusive did the rate fall below 20 per cent (see Table III).

Du Pont's cellophane pricing policy is consistent with the economists' assumption that a rational monopolist aims to maximize profits. This did not always call for a price reduction. In 1947 du Pont earned only 19.1 per cent before taxes and only 11.2 per cent after taxes on its cellophane investment[108]—the postwar low. Raising the average price of cellophane from 41.9 cents a pound in 1947 to 46 cents a pound in 1948 paid off. By May 1948 du Pont's operative earnings had increased to 31 per cent. At that time its division manager announced that "if operative earnings of 31 per cent is [*sic*] considered inadequate, then an upward revision in prices will be necessary to improve the return."[109] He suggested a schedule of prices which would increase operative

---

these deductions: 90 per cent as early as 1935 (GX 490, p. 6506) and during the second world war practically all, when the company was paying large excess profits taxes. Consequently, cellophane operating earnings may be thought of as primarily representing earnings on total cellophane investment before taxes, and cellophane net earnings as earnings after taxes.

The problem of empirically determining profit rates is subject to many pitfalls. However, the procedure used by du Pont to determine cellophane earnings is subject to fewer criticisms than are usually encountered in profit estimates. It is true that earnings may be understated somewhat because of expenditures not directly related to cellophane manufacture and sale as noted above. On the other hand, some might argue that actual earnings are overstated in some years and understated in others because operating investment is necessarily based in part on historical rather than replacement costs. This error is reduced by the fact that du Pont has increased its capacity periodically by substantial amounts, so that of its historical costs a substantial portion is always recent history. However, some of the most frequent and important shortcomings of profit estimates are not involved in our calculations; operating investment does not include assets capitalized in expectation of excess profits, nor has overcapacity broadened the investment base. Probably the most convincing argument as to the credibility of these earnings is that du Pont has no reason to delude itself as to what it is earning in making cellophane. The investment base which du Pont uses to calculate its rates of operating and net earnings is its estimate of the actual total investment involved in its cellophane operations. Such an investment base is considerably larger than that used by the Federal Trade Commission in its study, *Rates of Return (after Taxes) for 516 Identical Companies in 25 Selected Manufacturing Industries, 1940, 1947-52* (Washington, D.C., 1954), which uses stockholders' investment as its base. If this base were used in calculating rates of cellophane earnings they would undoubtedly be greater for all years. For example, in 1935, the year before Du Pont Cellophane was consolidated with du Pont, the latter's equity in Du Pont Cellophane was only $9,696,000. GX 490, p. 6504. If this were used as a base upon which to calculate du Pont's rate of earnings in that year, instead of that actually used in Table III, its rate of operating earnings would be about 60 per cent instead of 24.6 per cent

[108] One reason for the relatively low earnings in 1947 was du Pont's inability to put its new capacity at Clinton, Iowa into production as early as predicted. DX 372.

1949	n.a.	n.a.	35.2[t]	n.a.	n.a
1950	67,532	30,592[t]	45.3[t]	13,506	20.0[t]
	Average Rate of Return		34.4		24.2

* For definition of operating investment, operating earnings, and net earnings see footnote 107. Before 1937, investment and earnings figures include cellulose caps and bands, cellulose acetate, and adhesives, for some years. On the whole this inclusion decreases the rate of return figures for cellophane slightly, since some of these items were actually sold at a loss at times. The net effect is insignificant, however, since they represent such a small proportion of total earnings and investment—less than 5 per cent in 1935 GX 490, p 6507

earnings to about 40 per cent.[110] This was not put into effect until August 1948. Operative earnings for 1948 averaged only 27.2 per cent; but by 1949 they had increased to 35.2 per cent and by 1950 to 45.3 per cent. Operative earnings after taxes yielded 20 per cent on du Pont's investment in 1950.

Du Pont's pricing policy in the postwar inflation is also consistent with the theory of monopolistic behavior, but the record indicates that profit maximization was not the sole factor affecting price decisions. The division manager in suggesting price increases called attention to other relevant factors:

> 2. What effect, if any, will a price increase have on our case when it is heard before the Federal Judge? I have not covered this with our Legal Department but in view of the position they took last July and August, prior to the October increase, I am inclined to think they should be brought in for a discussion on this matter.
>
> 3. The du Pont Company may get some undesirable publicity from the press. A price increase on Cellophane could be looked upon as added fuel to the present recent spurt in the inflationary spiral and add to the present pressure for an increase in wages. This question is currently a live one at several of our Cellophane plants. Probably it would be in order to discuss this with Mr. Brayman.[111]

After considering these questions du Pont executives decided on the price increase.[112]

Cellophane's earnings record offers persuasive if not convincing evidence that du Pont has had monopoly power in selling cellophane. A comparison of du Pont's earnings from cellophane with its earnings from rayon lends force to this conclusion.[113] Despite the dissimilarity of the end products, several factors justify the comparison. Cellophane and rayon stem from the same basic raw materials. Both are radical innovations. Both were initially manufactured under noncompetitive conditions and both enjoyed substantial tariff protection. The same

[110] *Ibid.*, p. 7540.

[111] *Loc. cit.* Mr. Brayman was the director of du Pont's public relations department.

[112] In considering the probable effect of a price increase on cellophane earnings, the division manager stated the matter as follows: "Can we sell the capacity output of our plants? . . . The District Managers are divided in their opinion. . . . However, the majority of the District Managers, the Director and Assistant Director of Sales are of the opinion, barring a recession, the tonnage can be sold." *Ibid.*, p. 7539. Although this reasoning is consistent with that of a monopolist interested in maximizing profits, Judge Leahy cited it as evidence that du Pont did not have the power to raise prices arbitrarily. *United States v. E. I. du Pont de Nemours & Co.*, 118 F. Supp. 41, 179 (D. Del. 1953).

[113] Data are not available to compare du Pont's earnings from cellophane with the earnings of producers of other wrapping materials. These are without exception diversified firms producing a variety of products. However, the record discloses that in every year from 1935 through 1942 du Pont failed to cover costs in selling cellulose acetate film, which it sold in competition with two other concerns (GX 490 through GX 497).

business management produced both products. The French Comptoir shared in the management of both Du Pont Cellophane and Du Pont Rayon until 1929. Yerkes, president of Du Pont Cellophane, was also president of Du Pont Rayon. Presumably du Pont in controlling business policy for both companies was actuated by similar business motives.[114] Both products have had several reasonably close substitutes. The production and consumption of both increased phenomenally.[115] Cellophane and rayon have been similarly characterized by rapidly developing technology, rapid reduction in costs, and rapid decline in prices.[116] The chief difference in the manufacture and sale of the two products significant to the course of profits apparently lies in the structure of the rayon and cellophane industries. Although rayon manufacture began in this country as a monopoly, rival firms came into the industry promptly. American Viscose Corporation began as the sole domestic producer of rayon shortly before the first world war and du Pont followed in 1920. By 1930 these concerns had eighteen rivals. As late as 1949 fifteen firms occupied the field. Although the four largest firms in recent years have usually accounted for about 70 per cent of the total output and although most of the firms have generally followed a price leader, Markham from his painstaking and exhaustive study concludes that freedom of entry and the pressure of substitute products have made the rayon industry workably or effectively competitive.[117] The course of both du Pont's and the industry's rate of earnings supports this conclusion (see Table IV). Federal Trade Commission data reveal that in 1920, when du Pont first produced rayon, American Viscose Corporation, until then the country's sole producer, realized 64.2 per cent on its investment.[118] Although du Pont showed a loss in

[114] The district court found. "Same individuals were the principal du Pont executives in du Pont Rayon Co and du Pont Cellophane Co Same policies of improving quality, lowering cost of production, and reducing unit price to gain greater volume of sales were followed as to both companies"; and that du Pont's "price policy for rayon was the same as for cellophane" 118 F Supp at 86.

[115] United States consumption of rayon increased by about 320,000,000 pounds between 1920 and 1938 Jesse W Markham, *Competition in the Rayon Industry* (Cambridge, Mass., 1952), p. 230 Cellophane consumption grew by about 80,000,000 pounds between 1924 and 1938. DX 600, p. 1216.

[116] Rayon prices dropped from $6.00 a pound on February 1, 1920 to $0.51 a pound on July 29, 1938 Federal Trade Commission, *Investments, Profits, and Rates of Return for Selected Industries* (a special report prepared for the Temporary National Economic Committee, 76th Cong., 3d Sess.), 1941, p. 17985. Cellophane prices dropped from $2.51 in 1924 to $0.42 in 1938 DX 336, p 642

[117] Markham, *op cit*, pp 181, 206, 208.

[118] Federal Trade Commission, *op. cit supra* note 116, p. 17644. In this report the Commission's method of estimating rates of earnings on the basis of total investment is apparently similar to du Pont's method of calculating its operating earnings for its various divisions. See note 107 *supra*

TABLE IV.—INVESTMENT OF PRINCIPAL COMPANIES IN RAYON, INVESTMENT OF DU PONT IN RAYON, INVESTMENT OF DU PONT IN CELLOPHANE, AND ANNUAL RATE OF RETURN BEFORE TAXES ON THESE INVESTMENTS, 1920–1938

Year	Total Rayon Investment of Principal Rayon Companies (millions of dollars)	Du Pont's Rayon Investment	Du Pont's Cellophane Investment	Average Rate of Return of Principal Rayon Companies (per cent)	DuPont's Rate of Return on Rayon Investment (per cent)	Du Pont's Rate of Return on Cellophane Investment (per cent)
1920	$ 40.7			64.2		
1921	51.2	$ 2.9		42.0	(−2.1)	
1922	66.0	4.0		50.1	34.1	
1923	89.1	6.3		43.2	38.9	
1924	110.6	8.9		26.7	27.9	
1925	141.7	14.0	$ 2.1	30.6	34.2	36.7
1926	159.3	20.2	2.5	20.1	15.2	58.3
1927	166.7	24.4	2.7	25.8	27.0	44.8
1928	199.1	29.6	2.6	24.5	26.6	62.4
1929	228.0	38.4	5.1	18.1	19.0	55.8
1930	244.6	41.1	11.2	5.0	(−0.9)	39.9
1931	234.5	37.0	18.2	3.4	4.5	29.9
1932	223.2	33.5	21.6	1.5	1.2	18.0
1933	238.3	32.4	23.3	12.2	12.7	21.3
1934	249.9	38.7	24.0	6.9	8.6	24.9
1935	255.4	46.0	24.6	6.7	5.3	24.6
1936	267.0	50.0	26.3	11.5	11.0	29.1
1937	281.3	54.6	27.3	12.1	13.1	25.2
1938	296.6	61.7	30.7	2.5	4.2	27.5
Average Rate of Return				21.4	15.6	35.6

Sources: Rayon investment and earnings, Federal Trade Commission, *Investments, Profits, and Rates of Return for Selected Industries* (a special report prepared for the Temporary National Economic Committee, 76th Cong., 3d Sess.), 1941, pp. 17988, 17990, 17998. Cellophane investment and earnings based on Table III. Comparable data on total rayon investment and earnings are not available beyond 1938.

1921, its rate of earnings rose to 38.9 per cent by 1923. Thereafter its rate of earnings and those of the industry declined until by 1929 they had fallen to 19.0 and 18.1 per cent, respectively. When six more firms entered the industry in 1930,[119] average industry earnings fell to 5.0 per cent and du Pont suffered a loss of 0.9 per cent. During the following eight years du Pont averaged only 7.5 per cent on its rayon investment, and the industry as a whole put in a similar performance.

In striking contrast, du Pont with only a single rival in producing cellophane (and that rival's output closely geared to du Pont's) earned less than 20 per cent on its cellophane investment in only one depression year. From the beginning of the depression in 1929 through the succeed-

[119] Markham, *op. cit.*, p 47

ing recovery and the 1938 recession du Pont averaged 29.6 per cent before taxes on its cellophane investment. On its rayon investment it averaged only 6.3 per cent.

IV. *Conclusions*

Apparently the cellophane market does not conform to the Chamberlinian model in which substitutes are so close that no producer may long enjoy monopoly returns—a "sort of ideal" equilibrium adjustment with the demand curve tangent to the cost curve at some point above lowest average cost. It does not conform to Clark's model of workable competition wherein rival products and potential competition reduce the slope of the demand curve, or to Robertson's model wherein substitutes are so close as to result in a competitive price. Rather, cellophane is so differentiated from other flexible wrapping materials that its cross elasticity of demand gives du Pont significant and continuing monopoly power.

Du Pont has used its power with foresight and wisdom. It has apparently recognized that it could increase its earnings by decreasing its costs and prices, by educating its potential customers to the benefits of wrapping their products in cellophane, by improving machinery for packaging, by helping converters and packagers solve their technical problems. It has built a better mousetrap and taught people how to use it.

But du Pont has not surrendered its monopoly power. Its strategy, cellophane's distinctive qualities, and the course of its prices and earnings indicate this. Du Pont's strategy was designed to protect a monopoly in the sale of a product it regarded as unique, and its pricing policies reflected the judgment of its executives on how best to maximize earnings. We think its earnings illustrate Knight's distinction between justifiable profits to the innovator and unjustifiable monopoly gains. They have been "too large" and have lasted "too long."

THE TAXONOMIC APPROACH TO THE STUDY OF ECONOMIC POLICIES

By A. C. L. DAY*

All that is important in the study of economics is essentially concerned with the study of economic policies. To some degree or another, practically all economists are making statements of the form, "if you carry out such and such a policy, then you are likely to get these sorts of consequences." The number of economists who are solely concerned with completely detached analysis is very small, and even their thoughts are likely to be used by their colleagues as the basis of policy judgments. That this is so is probably quite right; there would be little justification either for the present number of economists or for the degree of respect with which they are regarded by the people who actually have to make decisions, unless they could provide fairly clear analysis and information upon which decisions could be based.

In these circumstances, it is important that economists should be clear about the nature of their statements on economic policy, the position of such statements in the study of economics as a whole, and about the best techniques for organizing the information that these statements can give. The purpose of this paper is to look into this question, with particular regard to the taxonomic, or classificatory, approach, which has been severely criticized in two powerful articles,[1] both of which were written as reviews of studies of economic policy which used that approach. The argument of this paper will be that the study of economic policy, by its nature, demands a use of the taxonomic approach, and indeed an extension of its use beyond its present employment.[2] That there are clear dangers in the use of taxonomy

* The author is lecturer at the London School of Economics and Political Science, temporarily on leave to serve as an economic adviser at Her Majesty's Treasury. This article was completed before he took up the government appointment. He acknowledges indebtedness to R. F. G. Alford, G. Morton, A. T. Peacock, A. W. Phillips and R. Turvey for criticisms and comments on an earlier draft of this paper.

[1] Milton Friedman, "Lange on Price Flexibility and Employment," *Am. Econ. Rev.*, Sept. 1946, XXXVI, 613-631. Reprinted in *Essays in Positivist Economics* (Chicago, 1953), pp. 277-300. H. G. Johnson, "The Taxonomic Approach to Economic Policy," *Econ. Jour.*, Dec. 1951, LXI, 812-32.

It should be emphasized that this paper is not intended to express differences with Friedman's "positivist" approach as expounded in the first of the *Essays*; with the fundamentals of that argument I am in agreement.

[2] In, for example, J. E. Meade, *The Theory of Economic Policy*, Vol. I, *The Balance of Payments* (London, 1951), and Jan Tinbergen, *On the Theory of Economic Policy* (Amsterdam, 1952).

is apparent, and there can be no doubt that recent work has not avoided them all; some of them will be considered later in this paper. Moreover, simply because of the extreme complexity and changeability of the economic system, a reasonably satisfactory theory of economic policy must be a very considerable undertaking, which can never be complete and will never satisfy everybody. No doubt the best method of procedure in making up such a body of theory is to fill in, in detail, the parts of the system which seem to be of most significance or practical value, while being clear about where that part of the theory fits into the whole.

The view of the opponents of the taxonomic approach is that "if economic theory is to be applied to problems of economic policy, this can most usefully be done within the context of a particular problem occurring within a particular environment. Only so will full justice be done to the complexities of policy problems, and adequate attention paid to the necessity of economic measurement."[3] Friedman is less directly concerned with policy and more with analysis, but his peroration follows essentially the same line. "A far better way [than the taxonomic approach] is to try to devise theoretical generalizations to fit as full and comprehensive a set of related facts about the real world as it is possible to get."[4] Both writers regard it as the function of economics to look at the available facts about a *particular situation,* to devise theoretical generalizations from those facts, and to test and use those generalizations by forecasting from them. This position is more clearly expressed in Friedman's article than in Johnson's, largely because the former develops his case on taxonomy at much greater length than the latter. Although the final position adopted by both writers is broadly the same, the issue is somewhat confused by the fact that the main body of Johnson's article does not appear to be attacking taxonomy as such, but inappropriate taxonomy (for example, Meade's failure to consider the influence of the terms of trade on expenditure).[5] This contradiction may not in fact be as sharp as it can appear to be: it can be argued

[3] Johnson, *op. cit.*, p. 828

[4] *Op. cit.*, p. 631.

[5] Much of Friedman's opposition is also directed more against misuse of the taxonomic approach than against the approach as such. With his attack on the creation of systems that cannot be empirically verified, there can be no basic disagreement. This, however, is by no means the whole of Friedman's position; the disagreement of this paper is with the view that the taxonomic approach cannot be a useful tool of analysis, which is an interpretation that can reasonably be made of Friedman's position. For Friedman, the taxonomic approach inevitably involves the use of illogical devices and specious reasoning; the substance of the position represented by this paper is that such dangers are always present in economic theory, that they are shown up particularly clearly by the taxonomic approach, that they should always be avoided if economic theory is to be useful, and that useful economic theory must frequently be explicitly taxonomic.

with force, as Johnson does, that the taxonomic approach necessarily involves a risk of such shortcomings. Nevertheless, there is a shift of emphasis in the last two pages of Johnson's article, and both in order to avoid the confusions that this can cause, and because Friedman develops his thesis in more detail, the main burden of the disagreement in this paper will be directed against Friedman.

The method to which both authors are opposed involves the setting up of a system of different possible kinds of interrelationships between various economic factors—the setting up of a system of different possible worlds. For Friedman and Johnson, our theories and our analysis of policies should be firmly rooted in the facts as they are known at a particular time.[6]

It is convenient at this stage to distinguish two different kinds of taxonomy; formally, one is a particular case of the other, but for the questions on hand the distinction needs to be made. On the one hand, there is taxonomy which consists of the classification, in the form yes/no, of the answers to a series of questions about whether there is a direct relationship between two magnitudes which we must take into account in considering a particular economic system.[7] The other form of taxonomy considers the different numerical values that can be used to describe such relationships. This second type involves more detailed knowledge; in addition to saying a relationship cannot be regarded as zero, an attempt is made to say more precisely what it is, in quantitative terms. The taxonomic method, fully employed, makes use of both of these kinds of classification. It considers the differing logical consequences when one considers a certain relationship present from those existing if it be assumed absent; and in addition it classifies the different sets of consequences arising from different strengths of the relevant relationships.

The antitaxonomic position expressed in Friedman's article is largely based upon what seems at first sight to be an attractive analogy drawn from the physical sciences. It would be possible, he argues, for astronomers to explore an infinite number of interrelations between a variable number of planets, each of which could be of any size or density. They could imagine up an infinite number of theoretical systems, whereas in fact there is only the one real universe. Therefore, Friedman argues, astronomers derive hypotheses from this one set of

[6] This point is clearly related to the well-known differences between the National Bureau and the Cowles Commission approaches. This difference does not seem to be the core of the issue under discussion here, however, in the Universities-National Bureau *Conference on Business Cycles* (New York, 1951), p. 114, Friedman takes a judicially conciliatory position between the two extreme views.

[7] These statements are essentially of the form of the "truth tables" of logical theory, and are also the basic principles of botanical taxonomy.

observed facts,[8] test them, and use, reject, or extend them as appears to be justified. This nontaxonomic approach, moving back and forth directly between the observed universe and theory, is the one which Friedman recommends should be used by economists.

Unfortunately, here is one of those cases where analogies from the physical sciences can be misleading for the social sciences. The physical scientist can take it as reasonably certain for most of his problems that he is in the same world today as he was yesterday. Once he has determined the acceleration due to gravity or the specific gravity of mercury, he can rely on their constancy for all time. (He cannot, of course, *prove* that they will remain constant). The economist, even if he can ascertain the numerical value of a structural relationship (and that may be difficult enough because of the familiar problem that he cannot isolate bits of the world in a test tube), cannot rely on its remaining constant. Physicists would have to be more taxonomic if they could neither be confident about ascertaining the acceleration due to gravity, nor be sure that it would remain constant. As far as the economist is concerned. there is a large number of possible worlds. By the time he has decided what sort of a world he is in, and then has developed a theory to describe it, the world he is describing is likely to have changed.[9]

This is not a difficulty that can be attributed solely to shortcomings in economic science. It is a consequence of the fact that the activity we describe as "economic" is intimately linked with the rest of social life. It is impossible to isolate economic activity from the rest of human activity in such a way that the influences of the latter on economic activity will be simple and predictable. Economics cannot be autonomous, because we cannot be sure what economic world we shall be in next year, even if we are fairly sure that we can describe today's. In particular, technological and political change can have strong effects on economic parameters. Studies of economic phenomena must inevitably be "open-ended" from the point of view of the economist; any attempt to draw up a complete system showing the loops of causa-

[8] It is not my purpose here to follow up the criticisms that can be made, on the basis of Popper's work, of Friedman's theory of scientific inference in the natural sciences. On the criticism of the validity of the inductive method in the natural sciences, and the arguments for the hypothetico-deductive method, see J. O. Wisdom, *Foundations of Inference in Natural Science* (London, 1952). It should be noted in this respect that the initial essay in *Essays in Positive Economics* shows considerable differences in Friedman's position compared with his earlier paper which is under discussion here

[9] Awareness of these facts does not imply that we must abandon the Galilean mechanics of the world of mathematical models; it means that we must accept the limitations of a system which does not necessarily include any absolutely reliable "physical constants." Of course, this should not be taken as implying that it is wise to swing to the other extreme; "all is flux" is not a suitable guiding rule for the economic theorist, because it leads to an acceptance of the impossibility of any theory.

tion relevant to economic affairs must include sections of the circuit which pass into fields which cannot be the direct concern of the economist, such as the fields of politics and sociology.

The intimate linkage between economics and politics provides a strong reason why the number of possible worlds facing the economist is multiple. Many aims of policy seem, or at least may seem, possible to the politician; the economist must take these aims into account as a part of his system and therefore has to consider many different possible systems. As has been pointed out before, the analogy with economics on the side of the "true" sciences should not be physics so much as engineering. The engineer frequently makes use of taxonomy, implicitly or explicitly; his recommendations vary in accordance with the surrounding conditions of his project, and in accordance with what he is asked to do.[10] On the other hand, he has the advantage that he usually knows his parameters and can frequently work with quite large margins of tolerance.

The differences between economics and physics, then, are manifold. Even if economists were sure what the relevant relationships are, they could not verify their magnitudes with any great accuracy; even if their magnitudes could be verified, it could not be relied upon for practical purposes that they would not change; and even if the structural magnitudes did not change, the aims of policy would. It should be apparent enough why economists, if they are to make statements about policies, must be taxonomic and allow for a wide range of possibilities.

The method of the physical sciences has been described as one of movement directly back and forth between reality and theory. This can be accepted as an approximate description of scientific method in the natural sciences, even if the inductive method is not regarded as a description of the process by which those sciences are developed, and if it is considered that the valid description is the hypothetico-deductive method, in which the starting point is not reality, but a mental framework into which one's observations of reality are fitted with a greater or less degree of success, the framework being modified in accordance with its degree of success. In the physical sciences, the problems are simple enough, identifiable enough, and permanent enough to be developed in this way, by direct movement between hypothesis and observation.

[10] It is a commonplace in engineering textbooks to employ taxonomy in the form of graphs or tables showing the different numerical values of one variable that will be associated with differing sets of values of other variables. The same techniques are frequently used in the recommendations of practising engineers, often in statements of facts which are closely akin to those studied by economists: for example, considering the various possible costs, under varying assumptions, of various processes and techniques.

In the case of economics, however, the use of this simple method of moving directly back and forth between reality and theory is likely to be less profitable. It is by no means useless. Immediate testing, by appeal to a fairly broad glance at reality, can show the plausibility of very general hypotheses, such as Keynes' view that part but not the whole of an increase in real income will be spent. Moreover, the refinement of econometric techniques may, in time, make direct movement back and forth between reality and theory the normal method of developing quite refined hypotheses in economics; for example, by giving exact numerical descriptions of the consumption function. Generally speaking, however, such techniques have not yet been developed very far, and it seems very doubtful whether they can ever give anything like a full description of anything like all possible (as opposed to conceivable) worlds.

The dilemma facing the economist when he has to make statements on economic policy is that while he must remain ignorant about the full details of all the possible and relevant economic worlds, decisions about economic policy still have to be taken, and he, as an economist, will be expected to give his opinion about such decisions.[11] Two dangers

[11] The nearest correlate of economics in the physical sciences in this respect is probably meteorology. (On this, see G. Morton, pp. 272 *et seq.*, in *Faster than Thought*, edited by Bowden, [London, 1953].) Rapid judgments have to be made about changing, and in detail quasi-unique, situations. On the other hand, meteorological data can be collected quite quickly in relation to the length of the forecast period, and the basic physical laws are constant. An interesting comparison between meteorology and economics from the point of view of a professional meteorologist is found in O. G. Sutton, *Mathematics in Action* (London, 1954), p. 106. "This intricate nature of the meteorological problem is perhaps better realised by a comparison, not with astronomy, but with economics. Both subjects deal fundamentally with problems of energy transformations and distributions—in economics, labour produces goods and other forms of wealth and meteorology traces the distribution of energy from the sun. Both systems are affected by complicated and seemingly capricious external influences. Economics has to reckon with man in his infinite variety, meteorology with effects arising from the irregular character of the surface of the earth and the uneven distribution of water vapour in the atmosphere. We are painfully aware that there is no universally accepted theory in economics and very little hope of establishing such a theory in the present generation. In plain language, economics is too difficult to be developed quickly into an exact science, and much of the political strife of today arises from the refusal of enthusiasts to admit this simple truth. We may go further than this. In problems of economic behaviour variations in human psychology introduce disturbances of an apparently irrational (and therefore unpredictable) kind into any planned system, and for this reason it is doubtful if a genuine mathematical description of the whole economic field, with the implication of exact prediction is possible. Much the same arguments may be applied to meteorology. To bring the weather within the scope of exact mathematical analysis demands the formation of something approaching a universal theory of atmospheric motions. It is only rarely that universal theories appear even in highly developed subjects like physics, and research, for the most part, is directed towards the exploration of limited fields as they become ripe for exploitation. Quite apart from this aspect, however, there arises the possibility (as in economics) of extraneous random influences. We do not yet know how far unpredictable elements such as sunspots or bursts of cosmic radiation may affect atmospheric motions; if they play a significant part, weather is subject to an inherent indeterminacy which makes real long-range forecasting impossible."

face him here. He may drift towards an anti-intellectualist position, by regarding economic policy decisions as purely a matter of judgment or intuition, about which the theorist acting in a purely intellectual manner can be nothing more than usefully platitudinous, sitting as a father-figure admonishing greedy children by impressing upon them that they cannot have their cake and eat it. The position of judgment and intuition in the making of economic policy is extremely important: but this attitude unduly narrows the range within which the intellect can operate. Alternatively, the economist can continue to use his intellect, but apply it directly to the past rather than to the present and future. He can analyze a past situation or development in detail, but leave to the civil servant or the economic politician the task of deciding how relevant the description is to present circumstances. This is perhaps what might follow if Friedman's advice were followed extensively, and theoretical generalizations were developed which described as full a set of facts about the world as is available. Inevitably, a full enough set of facts will only be available about the world that is rapidly receding into history. This should not be taken as implying an antihistorical bias. Historical analysis must inevitably be a large and useful part of economics, but it is by no means all.

The process of development of economic theory has been, and must tend still more to be, a more complicated one than the movement back and forth between the real world and hypothesis or theory that characterizes the physical sciences. The difficulty that immediately arises is that many different relationships may conceivably be regarded as important in economic analysis, and it is very difficult to check how important they are and how serious would be the shortcomings of a model as a basis for analysis of real problems if a particular relationship were omitted.

The first stage in which taxonomy can be useful in economics is, therefore, at the stage of pure theory: the stage at which hypotheses are set up. It is impossible to provide as immediate or as unquestionable "verification" of the hypotheses of economic theory as is usually possible in the natural sciences.[12] Only very broadly, and largely on the basis of intuition and introspection, can the economist test directly whether his hypotheses fit with reality. At this stage, taxonomy can organize the assumptions of different theories.

Economic analysis must, because of the difficulty of testing, move into another stage—that of the consideration of the logical entailments

[12] It must be remembered that, strictly speaking, scientific hypotheses are never fully "verified"; at best, we can fail to disprove them. Despite this, it is difficult to deny the immense difference in the extent to which "verification" is possible in the physical sciences compared with the social sciences.

that follow from various hypotheses. When the matter is put in this way, of course, the description of the methods of the natural sciences already outlined appears rather *simpliste.* The natural scientist also goes through this stage of thought, in order more easily to see whether the full implications of his hypotheses fit in with his observations of the universe.

It is after this stage that the economist, together with other social scientists and to a large extent with the engineers, more openly parts company from the pure natural scientists. The multiplicity and changeability of possible important relationships in economics, together with the immense difficulty involved in verifying any of them, makes taxonomy of the second type distinguished earlier a necessary tool in the economist's box. In any of the more complex economic problems, there arise doubts about what are the magnitudes of the important relationships that are involved. In addition, the ever-present uncertainties about what reactions will occur which are important but basically unpredictable; of these reactions, political decisions probably make up a large part.

The purpose of taxonomy at this stage is to organize these possibilities in as systematic a way as possible. In a way, this may seem an unexciting occupation; it possesses neither the intellectual stimulus of pure theory nor does it seem to be right down to earth in practical facts. All the same, this work, which Meade has described as tool setting,[15] is essential once the problems become at all complicated. Here, then, is the place of taxonomy in economic method: it helps to make clear what relationships are being regarded as significant, and how they will interact when the relationships are regarded as being of certain magnitudes.

The next stage in the process of economic analysis is the department of the applied economist, who receives from the pure theorist, via the tool-setter, an organized set of possible interactions of various relationships which may be important. His task is to look at the real world and attempt, as far as possible, to find out what are the actual facts about the relationships; to see which relationships do appear to be important in a given situation and what are their numerical values. Inevitably, he cannot do this work fully Evidence will be subject to differing interpretations. Some evidence will be unobservable. Much will be verifiable only within large margins of error: it will be possible to eliminate some but by no means all of the rows and columns in the matrices of possibility provided by the theory of economic policy.

This is the stage where purely intellectual tools must fail us. In so

[15] *Op. cit.*, p. vii

far as facts on relationships are not fully available, different views can still be held on what relationships are important, and about the magnitude of these relationships; there will be several hypotheses or theories, or branches of a theory. On the other hand, in so far as applied economics provides reasonably incontrovertible facts, theories can be modified or dropped, and the irrelevant categories of possibility can be discarded. This failure arises particularly because policy decisions must still be made even though the full facts may not be available. Judgment and intuition must come to the aid of the intellect; assumptions must be made even though the facts are not certain. Here we are very near to the world of the civil servant and the politician; but the economist still has his place in helping to make recommendations that cannot be justified solely by appeal to intellectual argument and verifiable experience.

It is here, in the field of political economy, that another stream enters fully into the pattern, a stream which must influence decisions but is alien to the economist qua analyst. This is judgment about what are the desirable aims of policy; what are the political desiderata? This stream is an essential part of the decision-making process; it lies outside the province of the economist as such; on the other hand, it is most unlikely to lie outside his whole personality, for the simple reason that most economists are to some extent interested in changing (or preserving) the world. For these three reasons, it is very necessary that when making policy recommendations political economists should distinguish as honestly as possible between the normative and the analytical element in their judgments. How frequently, for example, has discussion on the highest levels of the policies of the Labour governments failed to distinguish between criticism of their aims and criticism of the methods by which those aims were being pursued? At the same time the analytical judgments whch are made by the political economist cannot all derive from economic analysis as such. Political economy is a branch of political philosophy which involves extensive use of judgments made by economists, and which is frequently indulged in by people who are also analytical economists.

Another temptation that must be resisted by the political economist is the temptation to discard all analysis, except perhaps the simplest, because it cannot provide full or unequivocal answers. This seems to be what Jewkes recommends,[14] and may well be the practical anti-intellectual consequence of the Friedman-Johnson type of attack on taxonomy. The taxonomic method, combined with careful logical analysis and with accurate and sometimes inspired observation of

[14] *Lloyds Bank Review*, Apr. 1953, pp. 18-32.

reality, can provide the firm intellectual foundation on which economic judgments can be based. Unless it is organized taxonomically, the range of possibilities is likely to be so bewildering as to induce defeatism, or to lead to unprofitable controversies where disagreements about relevance, about logic, and about orders of magnitude are hopelessly confused. Assumptions about the future and about the imponderables in the present have to be made;[15] the only way in which they can be organized usefully is by explicit use of taxonomy.

In fact, it appears that a great deal of the most useful work already done in economics has involved a considerable taxonomic element, although often only implicitly. The way in which matters have often occurred has been for two possibilities to be allowed, but for one to be considered as more important than the other, so that it is followed up more energetically. The danger in this procedure, which must increase, as problems dealt with become more complex, is that the possibilities that are implicitly excluded may be regarded as important by someone else; or some other person may lay more emphasis on some other possible relationship. The controversy about the effect of wage cuts on employment is full of such pitfalls for the unwary.

The present trend of economic theory must make either for more pitfalls of the same kind, or for complete lack of comprehension for all but the most agile mathematically, unless very full use is made of the taxonomic approach. For example, analysis of two-sector models[16] leads very easily, if assumptions are at all complicated, to solutions in the form of mathematical expressions which are difficult to decipher and impossible to understand intuitively, simply because of their complexity. When more than two sectors are described (and there can be little doubt that further extension of the analysis of a three-country world is one of the most important needs in international trade theory) the solutions become almost unmanageably complex, and one must accept either taxonomy or defeat. Nor is this the whole of the matter; it is probably fairly generally accepted that two of the most important lines of future development of macroeconomics are into dynamic analysis, and into consideration of nonlinearities. Here, the mathematics becomes so complicated that general solutions are frequently impossible. All that can be done is to assume a given set of numerical values for the various relationships and then calculate a solution. Frequently, the calculation of any particular solution must be such a

[15] And, no doubt, mistakes will frequently be made: for example, the mistakes in forecasting postwar consumption on the basis of prewar data.

[16] Both in international trade theory and for the fuller description of a closed economy. On the latter, see Ralph Turvey, "Some Notes on Multiplier Theory," *Am. Econ. Rev.*, June 1953, XLIII, pp. 275-95.

lengthy process that it is possible only by electronic devices; the literature of this particular development is already beginning to grow.[17] In fact, it is practically impossible to say anything useful about analytical problems which are too complicated to be given a general solution, unless use is made of a taxonomic approach. By using taxonomic organization of these complicated problems, it is possible for the economist to obtain additional insight and understanding; on this basis, he can organize and develop the informed intuition, upon which most complicated policy recommedations must immediately be based.

The need, then, is not to throw taxonomy overboard, but to accept its real and growing significance and to point out the directions in which particular care must be taken in making use of this method. The theory of economic policy has to provide navigating tables to help policy-makers deal with the problems they meet. For two reasons, this metaphor of navigating tables seems to be a more useful one than those current. To talk in terms of maps[18] is to imply a very limited range of possibilities in a fixed, and in principle fully knowable, world; assumptions that this metaphor may do something to avoid. More important, it is suggested that the theory of economic policy could profitably present its solutions and its categories of possibility in the explicit form of sets of tables designed to indicate what will be the consequences of a change in one variable on the different variables that appear to be significantly related to it, on various assumptions about the sizes of these relationships.

Even in very simple models using comparative statics, assuming linearity in the relationships (*e.g.*, constant elasticities) and assuming small initial disturbances, such tables can be useful. As an example, the familiar Robinson-Lerner formula for exchange stability can easily lead to placing exaggerated emphasis on the stability conditions, and insufficient on the relative sizes of disturbances and effects.[19] Once comparative statics models start to become at all complicated, even if the linearity and small disturbances assumptions are retained, the need for a well-organized taxonomy, with tables considering the consequences of various numerical values of the relationships, becomes quite apparent. Many of the mathematical conclusions in the later parts of the Mathematical Supplement to Meade's *Balance of Payments* are of no clear significance in a purely mathematical form, and cannot conveniently be summarized verbally. Tabular or graphical representations of the various relationships considered, with each table or graph

[17] See the bibliography in A. Tustin's *Mechanism of Economy Systems* (London, 1953).

[18] See Jewkes, *op. cit.*, p. 29.

[19] On this point see my note "Devaluation and the Balance of Payments," *Economica*, Nov. 1950, XVII n.s., 431-37.

representing a particular model and each place in the table or point on the graph representing the consequences of a particular set of numerical values of the relationships, would provide a convenient and easily understandable summary of the various possibilities.

The obvious criticism of this recommendation is the amount of work that would be involved and the amount of paper that would be covered. This would be considerable: the work of the tool-setter of the constructor of navigation tables, is to some extent tedious. All the same, it is easy to imagine that the work involved is greater than it really is. The number of possible models is very large in relation to the number of relationships that are regarded as important; and since there can be no limit to the number of relationships that can be regarded as important, the work can never be finished. But this does not mean that the task is hopeless. In the first place, a large number of possible models deriving from a given number of important relationships will be logically irrelevant because the system will be under- or overdetermined, because the number of equations will not equal the number of the unknowns.[20] Secondly, it will be justified if circumspection is used to regard some models as more significant than others. There are dangers here, for example, of arrogating to oneself the duties of the applied economist or even of the politician, and of making improper use of the logic of inverse probability.[21] Care must be taken about these errors, but with proper care the task of setting up a useful set of tables can be brought down to manageable proportions. By classifying the tables in accordance with the presumptions of the models they represent, it should be possible to see at a glance what is assumed and what is not assumed to be a relevant relationship in any particular model. At this first level of classification, it is made clear what relationships are considered relevant in different models; at the second level, the consequences of different magnitudes of the relevant relationships.

The system can never be complete, because it is always possible to bring in additional relationships which may be regarded as relevant. For example, there is Johnson's criticism of Meade, that he fails to take account of the terms-of-trade effect on expenditure out of a given money income. Each such additional relationship complicates the general algebraic form of the solution substantially, and soon leads to unmanageable expressions. As has been already said, the only possible reactions at this stage are to accept defeat or explicit taxonomy.

Any further degree of complication beyond that attained in Meade's

[20] It is wise not to exaggerate the importance of this limitation, however. Since the number of relationships which can conceivably be regarded as important is infinite, the number of conceivably relevant models is also infinite.

[21] See Friedman, *op. cit.*, p. 625.

Balance of Payments can only be satisfactorily dealt with by classification of particular numerical solutions for particular sets of relationships. This conclusion applies with some force where the complication is an extension from a two-sector model to a multisector model, because although matrix algebra can supply solutions, such solutions in themselves do not help political economists very much. Still more does this conclusion apply when the extension is to cases where dynamic conditions are considered, and where nonlinearities are allowed.

Friedman and Johnson criticize the taxonomic method because it may lead to undue simplicity; the true position is that taxonomy is desirable because it is the only way of dealing with complexity, and of allowing for the importance and the uncertainties of economic measurement. The criticisms they bring against the taxonomic method as such are really almost entirely criticisms of economic analysis as such, or at any rate of oversimplified economic analysis. An apparent weakness, and a real strength, of taxonomy is that it shows up the shortcomings of oversimplified analysis. In so doing it points the road to be followed, and it provides the means by which we can proceed along that road.

The great strength of taxonomic arrangement of solutions, whether arrived at mentally or electronically, is that it is able to deal with these two major shortcomings of traditional macroeconomics. On the one side, A. W. Phillips' recent study[22] shows how taxonomic methods can present valuable insight into dynamic processes; on the other, the work of Tinbergen[23] and of Manne and Frankovich[24] are recent examples of indications of the possibilities of considering nonlinearities. The constant elasticity assumption is a useful one, and can be justified in accordance with Occam's Razor, but it is certainly not always justifiable, and involves dangers of imposing the limitations of our minds on reality. Where this assumption is not justified, it can be abandoned without impossible difficulties, if one is willing to use calculations of particular solutions for particular numerical values. Another way in which nonlinearities may be important is mentioned by Tinbergen: limiting conditions may apply to particular variations; in formal terms there may be kinks in some functions after movement of a certain magnitude away from the initial conditions. Consideration of such kinks is likely to be essential once the infinitely-small-changes assumption is dropped. The point of all this is that, while simple theories are desirable when they are adequate for the task on hand, there are many cases when it is all too clear that they are inadequate. The only positive way of

[22] "Stabilisation Policy in a Closed Economy," *Econ. Jour.*, June 1954, LXIV, 290-323.

[23] *Op. cit.*

[24] A. S. Manne and J. M. Frankovich, "Electronic Calculating Methods for Solving Excess Capacity Problem," *Rev. Econ. Stat.*, Feb. 1953, XXXV, 51.

dealing with these shortcomings is to complicate the models and organize the information they give taxonomically.

All this not to deny that there are dangers inherent in the taxonomic approach; these have been excellently analyzed by Friedman. Perhaps the biggest danger is that of using classifications with no empirical counterpart. Sometimes that procedure will be justifiable, as a reasonably close approach to reality; but extreme caution must always be used. The taxonomist must always be aware that his categories of possibility must be fitted against the test of observation of the real world, by the applied economist. This means that it may often be wiser to decline relationships in terms of actions of economic agents, rather than in terms of effects, with the exception that definition by effects may always be justified if it summarizes a set of relationships which are explained elsewhere, as in a more detailed model. If care is taken to see that relationships do have empirical counterparts, then the taxonomic model is subject to empirical testing. It is true that if it includes every conceivable possibility the model as a whole must include reality, and therefore cannot be contradicted as a whole.[25] But in significant senses a taxonomic model can be tested; relevant relationships can be shown to exist which are not in the model; some of the relationships explicitly included in the model may be shown to be unimportant and the parts of the model that are particularly important can be thrown into relief by attempts to define the order of magnitude of some of the relationships. Moreover, if care is taken to ensure that all the categories have empirical counterparts, it is possible to test which alternative within the total system is nearer to reality, in so far as empirical information can be obtained.

The danger of lack of clear empirical counterparts, with its ally implicit theorizing, is the greatest enemy of taxonomy, as of all economic analysis; there are also others, which it is worth listing. Care should be taken to be quite explicit about what one is doing when one steps outside the particular narrow part of the establishment of economic knowledge which is the province of the economic theorist. In particular, care should be taken to avoid introducing ethical and emotive judgments into purely analytical work; psychologically such complete separation is almost impossible, but honest taxonomy combined with self-awareness in the analyst can make such judgments

[25] *Cf.* Friedman, p. 628 This criticism can be overrated as a criticism of taxonomy as such. A statement of the form "it is either true or false that the sun is ten million miles from the earth" can be justifiably attacked on Friedman's lines. There can be no doubt that statements of this type have been used as the basis of unprofitable economic theorizing. But it cannot be said that taxonomic statements in economics are generally as sterile as this statement, especially in view of the lack of verifiability and the changeability of economic magnitudes which have already been discussed.

stand out for what they are.[26] Similarly, clearly organized classification can make judgments about facts on relationships stand out apart from analysis of the consequences of particular possible relationships. The fact seems to be that it is not that taxonomists are particularly subject psychologically to the dangers of "casual empiricism" and the "invalid use of inverse probability,"[27] but that these are the traps that beset all economic theorists but which are made particularly clear when the taxonomic approach is used. Similarly, taxonomy, unlike *ad hoc* theorizing, leaves perfectly clear the factors that one has considered, and therefore makes it quite obvious what one has not been able to consider.

These dangers attaching to the taxonomic method are real enough, even though they apply for the most part to all theorizing in economics. Nevertheless, useful advances in economic knowledge and useful influence on policy demand that the taxonomic approach should be given its proper place, to deal with problems that are beyond the powers of *ad hoc* theorizing or unaided intuition, and in which empirical verification is possible only to a very limited extent. Taxonomy permits the development of theories complicated enough to approximate to reality, it shows up the exact limits of our knowledge and the extent of our ignorance, and it allows us to organize and systematize what we can know about the uncertainties of the past and present and the immense range of possibilities of the future.

[26] Indeed, on the importance of such psychological motivations in some of the most important advances in economic theory, see Lange, "On the Scope and Method of Economics," *Rev Econ. Stud.*, 1945, XIII, 24.

THE IMPACT OF LABOR DISPUTES UPON COAL CONSUMPTION

By C. LAWRENCE CHRISTENSON*

A rather common view of labor disputes in the bituminous coal industry is that they represent interruptions of production that have seriously reduced the supplies of coal for consumers. It is this view that is the subject of the current article. It is a sequel to an earlier study[1] which set forth the theory of the offset factor and applied it to an interpretation of the relation of time losses from labor disputes to the production of bituminous coal for the eighteen years 1933-1950.

Given a dispute limited to a portion of a multifirm industry with a common market and a margin of unused capacity outside the area of the dispute, the impact upon production might be totally and immediately neutralized by simple shifting of orders from firms concerned in the dispute to those which are not so involved. This is the offset factor in its current-transfer form. An empirical test showed that in bituminous coal mining after 1939, the growth of unionism and the shrinkage in unemployment brought a weakening in the power of current-transfer to cushion the impact of labor disputes upon the production of coal.

As the power of current-transfer is restricted, however, that of the time-shift form of the offset may become greatly augmented. Even if disputes encompass an entire industry so that current-transfer disappears, there may still be possibilities of great expansion in output before a dispute begins, and reclamation after the event: the anticipatory and retroactive features of the time-shift form of the offset factor. The record for 1942-50 showed that the offset factor had been in effective operation especially in the form of anticipatory time-shift. Hence U. S. coal production reached levels considerably above those for

* The author is professor of economics at Indiana University He acknowledges aid in collection of materials from J. A DeCarlo and W. H. Young of the Bureau of Mines, Loretta Nolan and Ann Herlihy of the Bureau of Labor Statistics, Sterling McMillan of Western Reserve University, J. A. Thompson of the Coal Trade Association of Indiana, and John L. Lewis of the United Mine Workers For critical comment on an earlier draft he is indebted to Osmond Harline of the University of Utah and to his colleagues, Roland Davis and Henry Oliver. [1] C. L. Christenson "The Theory of the Offset Factor," *Am. Econ. Rev.*, Sept. 1953, XLII, 513-47.

earlier years even while the amount of dispute time losses also was passing the highest recorded magnitudes.

Although this finding is accepted, it still does not follow that the large volume of coal produced during 1942-50 was sufficient to protect coal consumption from being impaired by labor disputes. In answering that question the matter of coal stocks relative to consumer requirements becomes crucial. Coal is a bulky commodity and about half the problem of making it available for consumer use is in getting it delivered. Hence, for practical purposes we may say that coal, once mined, is always stored by consumers or dealers. These stockpiles insulate against consumer hardship if interruption of deliveries results from mine production stoppages. It will be our central objective to examine these compensatory reserves in some detail.

First, however, some classification of consumers is required. Preliminary examination reveals great variations in consumption and suggests at least three different ways of classifying coal consumers:

1. As to purpose of use: (a) productive-use consumers (*e.g.*, plants making durable goods); (b) final-use consumers (*e.g.*, households, schools or hospitals that burn coal for heating); and (c) compound-use consumers (*e.g.*, railroads using steam locomotives to supply freight as well as tourist passenger service).
2. As to availability of coal supplies: (a) market-access consumers (users that must buy coal from commercial mines); (b) direct-access consumers (industrial establishments operating their own coal mines); and (c) intermingled-access consumers (*e.g.*, railroads buying coal from on-line commercial mines).
3. As to continuity of coal use: (a) year-round consumers (*e.g.*, steel mills maintaining continuous operation); and (b) intermittent consumers (some industrial establishments, as well as households, that discontinue furnace use during summer).

This way of classifying consumers cannot allow for the actual variegated pattern of coal consumption. Neither can the available statistical record be fitted neatly into this classification. However, it is important for our analysis. It serves immediate warning that interruptions in coal deliveries will not be of uniform importance to all consumers, since both the possibility and relevance of compensatory reserves may be expected to vary, and hence the significance of the offset factor will also vary, for different consumer groups.

The consumption record used here is that which the Bureau of Mines has broken into eight consuming classes. Three of these (cement plants, steel mills, and coke ovens) are close approximations to productive-use consumers shown in our outline, while three others (electric power utilities, railroads, and the miscellaneous group called "other indus-
Source Mineral Market Reports, Bureau of Mines

Chart 1. Amount and Distribution of Bituminous Coal Consumption
(four minor-dispute years)

trials"—these latter hereafter labeled "general industrials") contain mixtures of both productive- and final-use consumption. The remaining two represent still more heterogeneous composites. One is the estimate of total quantities of coal moved by retail dealers and the other is the amount of foreign shipments either for export or for use as bunker fuel. The small amount going into bunker fuel is similar to coal used by railroads, but there is no way of identifying the use of export shipments. Classification of coal moving through retail yards is not comparable with the other records of consumption, and identification of its specific use involves speculation. Retail yard deliveries are not truly estimates of current consumption at all but rather records of shipments for future use. Some such shipments go to small industrial plants, but probably most of them are for heating residential or small commercial and public buildings, hence should be considered as final-use consumption.

A summary review both of the aggregate volume of coal consumption and the relative importance of each of these large consumer groups in four minor-dispute years is presented in Chart 1.[2] The shrinkage of

[2] The term major-dispute month, as used here, means a month in which such recorded time losses in the coal mines amount to 300,000 or more man-days. A major-dispute year contains one or more such months while minor-dispute years contain no month with lost time of that magnitude. For an industry with 400,000 production workers, the bench mark of 300,000 man-day losses amounts to a loss of one day of working time for 75 per cent of the force. See Christenson, *ibid.*, p. 517.

CHART 2. MONTHLY COAL CONSUMPTION—1943-53

total annual consumption from a peak of about 600 million tons in the war year, 1944, to a little over 450 million in 1953 was accompanied by substantial shifts in the relative position of the separate consuming groups.

Most prominent of these shifts is the both absolute and relative increase in the importance of electric power utilities along with a concomitant decrease in the position of railroads as coal consumers. Similarly, but a little less striking, is the increased consumption of coal
Source. Calculations from data of Weekly Coal Reports, Bureau of Mines

CHART 3. MONTHLY COAL CONSUMPTION IN COKE OVENS AND STEEL MILLS, 1943-53

by coke ovens and the more moderate reduction in coal use by general industrials. Steel mills as primary users of coal (apart from their coke consumption) have about held their own in absolute tonnage. Cement plants, although never large users, have increased both their absolute and relative positions. Both absolute and relative amounts passing through retail yards have shrunk considerably in the years since the second world war.

I. *Seasonal Patterns of Coal Consumption and the Timing of Disputes*

A. *Seasonal Patterns of Coal Consumption.* In examining the adequacy of reserve stocks as shelter against the impact of disputes upon coal consumption, the initial step is to seek some independent

measure of consumption requirements which may be regarded as normal, without distortion by production stoppages growing out of labor disputes. Since we do have seasonal temperature changes and since coal is a source of heat, the seasonal patterns of consumption and how the timing of labor disputes is related to such patterns are salient elements of our problem.

Separate twelve-month moving averages of actual consumption for each of the consumer groups were made for the entire twenty years, 1934-53. From these computations the figures for the seven years 1936, 1938, 1940, 1942, 1944, 1951, and 1952 were then used to construct individual seasonal indexes for electric utilities, general industrials, and railroads. Except for 1952, no major dispute time losses occurred in any of these years. While the time loss of a little over 2 million man-days in September 1952 injected an irregularity, there was no showing that consumption for any of these three groups was distorted by it.

For steel mills and coke plants there were the special problems of the major labor dispute in the steel industry in 1952, and the recession of 1938. Hence, for them seasonal indexes used are based on the years 1936, 1940, 1942, 1944, and 1951 instead of seven years of consumption records. These seasonal indexes for each of the five industrial coal users accounting for more than 75 per cent of total known consumption in 1953 are given in Table I.

Table I reveals some interesting differences in the seasonal consumption patterns. The amplitude of the seasonal swing is greatest for the general industrial consumers and least for the by-product coke ovens. The peak consumption month tends to be February, although electric utility and coke plant consumption are a little higher for January. The lowest consumption month is July for general industrial consumers, railroads, and steel mills. Coke plants and utilities, both with narrow amplitudes, reach minimum levels of consumption in March and April respectively. Disputes falling in March or April evidently take place when consumption has reached its minimum levels for some industrial users and started on the downward course for others.[3]

The indexes were next used to deseasonalize the actual consumption records of the period 1934-53. The result of these calculations, limited to the eleven years 1943-53 to simplify presentation, appear in Charts 2 and 3. This span covers all the major-dispute years since the orbit of unionism reached its widest limits with complete acceptance by consumer-owned mines at the close of 1941.

Chart 2 brings together for ready comparison consumption records

[3] A minor exception is cement plants which accounted for a little less than 2 per cent of total bituminous coal consumption in 1953. Their consumption pattern is highest during the summer months of intense building activity and lowest during the winter months.

TABLE I.—SEASONAL INDEXES OF COAL CONSUMPTION

	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Electric utilities	109	107	96	89	89	93	96	102	103	106	107	107
General industrial consumers	118	121	110	101	88	85	80	84	87	98	109	116
Railroads	111	112	105	99	93	89	88	92	95	101	106	108
By-product coke plants	103	102	97	99	100	100	100	100	100	100	101	102
Steel mills	117	119	108	98	92	88	86	90	90	96	104	112

Source. 12-month moving averages using Bureau of Mines data for minor-dispute years. Considerable experimentation preceded preparation of this table All consumption (and production figures used later) were calendar adjusted so the expression "actual consumption" (or "production") always refers to these standardized monthly records After construction of consumption trend lines, crude seasonal indexes for each of the consumer groups were then made Later, twelve-month moving averages of actual consumption figures for each of the groups were broken into segments separating the major from the minor dispute years following the pattern of my earlier study but adding another segment (1951–52) to bring the materials more nearly down to date (see Christenson, *op cit.*, pp. 528–29; 542, n 27). Ratios of actual consumption to these twelve month moving averages were computed, and separate seasonal indexes for each of the segments for the different consumer groups were matched against each other This led to selecting the minor-dispute years as basis for the seasonal indexes which were finally used Rank correlations of the four final indexes used with those for each of the separate major-dispute year segments are as follows:

Years of Index	Electric Utilities	General Industrials	Railroads	Steel Mills
1933, 1934, and 1935	84	.96	.94	.57
1937, 1939, and 1941	.71	90	89	.92
1943, and 1945	81	87	90	.98
1946, 1947, and 1948	92	.76	.92	90
1949, and 1950	88	94	81	.87

of the three groups later presented in Charts 4, 5, and 6. These are predominantly market-access consumers, and are also those for whom the same seven years were used in construction of seasonal indexes. Chart 3 deals with users who are largely, but not purely, direct access consumers, and for whom the indexes rely on records for only five years. Since application of the coke plant index to actual consumption almost reproduces the original materials, only actual consumption for this group has been charted. Steel mill consumption of coal, however, does exhibit a clear seasonal swing not as wide as that for general industrial consumers. This is related to seasonal swings in steel ingot production shown years ago by Kuznets.[4] Although in recent years the high level of industrial

[4] Simon Kuznets, *Seasonal Variations in Industry and Trade* (New York 1933), pp. 252, 289-90, 299. Kuznets found that steel production before 1930 showed primary seasonal peaks in March and secondary in October, with troughs in July and December (p 252). The minor-dispute years, 1942, 1944 and 1951, are good periods to examine and to observe

output has reduced the amplitude, evidence of seasonal fluctuation still remains.

Distortions of seasonal patterns by other forces are clear. Even without numerical refinement both the general business cycle factors and the comparative consumption trends for the individual groups are evident. The participation in retreat from war production, and in reconversion which follows in 1945-46, is seen for all industrial consumers. So too is the common share in the postreconversion slump of 1949-50. The swelling wave of steel production during and after reconversion with the insistent reliance upon coking coals and the moderate decrease in the direct use of coal in steel mills appears in Chart 3.

Understanding of seasonal influences is of substantial significance for our study of compensatory reserves in two ways. First, stockpile ratios to consumption are a function of the consumption requirements as well as of the physical volume of reserve stock tonnage. Second, reserve stock tonnage which initially depends on mine production rests also upon the character of coal delivery facilities. The seasonal character of the latter is emphatic in the complete stopping of cargo shipments with the freezing of the Great Lakes; but to a lesser extent rail and truck shipments also become more difficult during winter months. This inverse correlation between seasonality of consumer demand and ease of delivery makes a substantial contribution to the need for stockpiling.

B. *The Timing of Disputes.* Against this background of seasonal variations we need to examine the actual timing of labor disputes in the mines. Table II gives a chronological listing of major dispute months for two decades divided into separate groups: those which came before August 1st, and those during the last five months of the year.

Of the 240 months in the period 1934-53, 38 involved dispute time losses in excess of 300,000 man-days. Twenty-one of the 23 major-dispute months on the left side of Table II fall between the beginning of spring (March) and the end of July when consumer demand is normally low. The other 15 in the right section of Table II, need to be differentiated in more detail. Four (in 1941 and 1945) involve time losses concentrated in the consumer-owned mines and hence could not have directly limited coal use by market-access consumers. Four of the remaining 11 are from the postreconversion slump year of 1949 when receding aggregate industrial demand for coal made the end of that year resemble, but of course not duplicate, the seasonal shrinkage customarily occurring in the spring. If it is true that seasonal amplitudes tend to be damped during periods of high-level operations, it also ap-

how this pattern of steel production has persisted, even though it was considerably damped since Kuznets wrote See also steel ingot production line in Chart 8.

TABLE II.—MAJOR-DISPUTE MONTH TIME LOSSES IN BITUMINOUS COAL 1934–1953

Year	Before August 1		After August 1	
	Month	Man-Day Losses in Millions	Month	Man-Day Losses in Millions
1934	April May	.97 .35		
1935			September October	2.0 .65
1937	April	.97		
1939	April May	4.2 2.8		
1941	April	5.2	September October November	.30[a] .31[a] .55[a]

[a] Supervisory and captive mine disputes.

pears that during a year of continuing general recession business lethargy saps most of the strength in the normal fall upswing before it has a chance to gain much momentum. This may easily go so far as to make the usual upturn only a small elevation above the summer trough. Such was indeed the 1949 pattern for much of American industry, and it was certainly the character of consumption for most of the industrial users of coal. December 1949 consumption instead of being near that for January, hardly reached that of April or May for any of the important consuming groups (see consumption lines of Charts 2 and 3). Hence the 4 major-dispute months of 1949 which came late in that year were almost as if they had appeared in the spring from the standpoint of their relation to the level of consumption. January and February, it should be noted, never appear as major dispute months except in 1950, and in this case they may be viewed as showing a moderated continuation of the lethargic industrial atmosphere of December 1949.

The seven months which remain, each with its millions of man-day losses, are:

Sept. 1935—2.0	Oct. 1943—0.57	Nov. 1946—2.3	Oct. 1952—2.1
Oct. 1935—0.65	Nov. 1943—2.1	Dec. 1946—1.7	

These seem to be the major-dispute months on the right side of Table II for which it cannot be said that general recession reduced an otherwise rising winter demand. Hence they must be subjected to special scrutiny.

The months just mentioned show a combined total time loss of almost 11 million man-days. If we leave out about 4.5 million man-day losses for disputes concentrated on the supervisory force or in consumer-owned mines, time losses for all other major dispute months of our two decades will add to just under 70 million man-days. Put more emphatically, over 85 per cent of time losses charged to labor disputes in coal mining during the two decades since 1933, were synchronized either with seasonally falling demand or business recession. This is a primary fact to be reckoned with in determining the adequacy of compensatory reserves. Certainly stockpiles held during such periods will not need to be of the same magnitude as would be required when consumption is expanding.

II. *Consumption, Reserves, and Market Access*

A. *Interrelation of Consumer Patterns.* This chronology of consumption and disputes needs supplementation by a picture of the aggregate monthly reserves of the separate consumer classes. This is first presented for the three groups shown in Chart 2. In 1953 they

accounted for about half of the total bituminous coal consumption. They are interrelated in that an important function of the electric power utilities and railroads is to provide service to the general industrials. For the most part they are all market-access consumers but there are significant qualifications. General-industrial consumers probably are more completely market-access consumers than are the electric power utilities or the railroads. Very few of them own any coal mines, nor are their operations geographically so located as to provide special availability of coal supplies. Some electric power utilities, however, are favored with ownership of coal mines and with physical location which distinguishes them from other users of coal who must turn to the commercial market.[5] About 10 per cent of coal used in 1950 by electric plants was supplied by company-owned mines. Even part of that which comes from independently operated mines represents fixed commitments from some mines based on long-term contracts. This may furnish special access not shared by hand-to-mouth industrial buyers.

In the coal-consuming family, railroads are blessed by having supplies within especially easy reach. Roads having direct access through title to coal fields, produced about 20 per cent of total coal used by railroads in 1950. However, considerably more than half of this was in the hands of four large western roads,[6] and hence could not influence greatly the distribution of coal supplies in the industrial areas east of the Mississippi River. More important than coal ownership is that the railroads are common carriers. This fact has two aspects bearing on our problem: the first is that by preparing to serve the public they also serve themselves. Roadbeds passing through the mining areas make possible what the coal trade calls "on-line railroad" sales. Moreover, by interchange connections with other roads having such facilities, the railroads possess an element of direct access even though they may be commercial buyers. The second is that as common carriers one important part of their coal consumption requirements is immediately reduced when coal shipments are curtailed. Hence, in their insulation

[5] A case in point is the extensive coal holding near the Dresser generating station on the Wabash River of the Public Service Co. of Indiana, Inc. Sometimes such companies may still prefer to turn to the commercial market for part of their coal in order to preserve their own resources or because their most convenient reserves are exhausted. See *1952 Annual Report of Public Service Co. of Indiana Inc.*, p. 7.

[6] The largest coal mining railroad is the Union Pacific with holdings in Wyoming. It is followed by the Northern Pacific and the Milwaukee Road with properties in Montana and Washington. These three account for about half the "captive" railroad tonnage. The Chicago and Northwestern mines in Illinois account for another 10 per cent. The remaining 40 per cent of railroad production (all east of the Mississippi) is that of the Norfolk & Western, the New York Central and the Erie Railroad. See *Keystone Coal Buyers Manual* (New York, 1954), p. 596.

against the impact of the interruption of coal mining, the railroads occupy a special position.

B. *Compensatory Reserves of These Three Groups.* The relation of dispute time losses to the consumption and reserves of these three groups is shown in Charts 4, 5, and 6. The bars in each of the three charts showing time losses for all major dispute months of the two decades, are drawn to a uniform scale shown on the right in millions of man-days. The numerous small losses of minor dispute months are disregarded. Scales shown on the left represent the monthly consumption and beginning-of-month coal stocks in millions of tons.

The calendar-adjusted monthly coal consumption figures shown in the continuous thin line on each of the charts are plotted as of the middle of each month. Coal stocks, plotted as of the beginning of each month, appear in a series of dots representing the unadjusted stock figures as reported by the Bureau of Mines. The figures of electric power production (Chart 4) in billions of kilowatt-hours, and those for freight car loadings in millions of cars (Chart 6), similarly appear as heavy lines. Coal and coke car loading, however, are separated from all other freight loadings, and these are shown by the heavy broken line. No production figures comparable to kilowatt-hours or freight car loadings are shown for the general industrials (Chart 5). The broad inclusiveness of the Federal Reserve industrial production index makes it inappropriate for our purposes and a suitable independent index could not be devised.

C. *Relations of Disputes to Stockpile Ratios: Market-Access Consumers.* Comparison of individual group consumption patterns was made possible by Charts 2 and 3 (pp. 82, 83), but for this study the deseasonalized consumption records shown in the dot-marked lines are more important. If the seasonal patterns of the minor-dispute years used for calculation of the indexes were continuously repeated and left undisturbed by any other elements, then the dot-marked line of Charts 2 and 3 would cross the recorded consumption line in March or April and would lie above that line for all spring and summer months until crossing the consumption line again in the fall. Reference to the charts reveals no such simple pattern. Each of the groups shows elements of seasonal variation in all years, but no uniformity.

The purpose of deseasonalization is to aid in testing the impact of disputes upon consumption. Our seasonal indexes based on figures for minor-dispute years show high correlation with similarly constructed ones using records for major dispute years, but the possibility of impaired consumption may still be concealed. Also since other forces have modified seasonal patterns our use of the deseasonalized figures must be

discriminating and supplemented with such other aids as we can find.

The primary test used is the ratio of recorded coal stocks for each separate consumer group (Charts 4, 5 and 6) to deseasonalized consumption. All reserves for future use must be acquired in advance of exact knowledge of what the future will be. A calculated ratio of 100

CHART 5. MAJOR-DISPUTE MONTH MAN-DAY LOSSES IN COAL MINES RELATED TO GENERAL INDUSTRIAL: COAL CONSUMPTION, COAL STOCKS

per cent represents a stockpile for that consumer class adequate to maintain a subsequent month's actual consumption adjusted by our seasonal index. Such ratios would always understate actual reserves when deseasonalized consumption was in excess of actual consumption and overestimate them during months when deseasonalized consumption was less than actual consumption.

CHART 6. MAJOR-DISPUTE MONTH MAN-DAY LOSSES IN COAL MINES RELATED TO RAILROAD: FREIGHT CAR LOADINGS, COAL CONSUMPTION, COAL STOCKS

If consumers kept a constant ratio of stocks to accurately anticipated consumption, then calculating stocks as ratios of deseasonalized consumption would transfer the seasonal pattern to the stockpile ratios. Under such ideal circumstances increases of these ratios above the seasonal course, just before or during dispute months, would indicate consumers' reliance on the anticipatory feature of the offset factor by

Ratio Calculations all based on data from Weekly Coal Reports, Bureau of Mines

CHART 7. RATIOS OF CONSUMER STOCKS TO DESEASONALIZED COAL CONSUMPTION WITH MAJOR-DISPUTE MAN-DAY LOSSES IN SOFT COAL

augmentation of compensatory reserves. Disruption of standard seasonal consumption patterns, however, and lack of any conclusive evidence that all consumers do tend to maintain constant reserve ratios preclude expectation of such neat results.

With the warning against anticipation of exact measurement, Chart 7 is introduced. Here is a twenty-year view of the monthly ratio of coal stocks to deseasonalized consumption for the three industrial groups that are primarily market-access consumers. Superimposed are the bars showing man-day losses in major dispute months.

Examination of that portion of Chart 7 which covers the years prior to 1943 reveals that all the major-dispute time losses, except for those of 1935 and 1941 (the latter in the consumer-owned mines), fall in April or May. October 1935, with 650,000 man-day losses, is the only one of the major-dispute months of these years before 1943 when deseasonalized consumption is slightly under the actual consumption for all three of these consumer groups. During all major-dispute months prior to 1943, and for all three of these consumer groups, the calculated stockpile ratios may be taken as conservative estimates of the relation of inventories to requirements. Once this is known, attention can be directed at the ratio calculations themselves.

It is not true that the calculated ratios rise at the beginning of the major-dispute months for all three of these consumer groups in the years before 1943, but there was some movement in that direction. In so far as such movement did occur, it was the railroads, customarily with the lowest reserve ratio, that led the movement. During all years prior to 1943 railroad stockpile ratios were pushed up sharply in advance of major-dispute months. Although ordinarily carrying reserves calculated at rarely above 95 per cent and frequently as low as 60 per cent, the railroads moved to more sheltered positions with ratios in the major-dispute months usually well over 100 per cent. Their added protection was, of course, partly due to reduced requirements because of curtailed coal shipments. The upward movement of ratios for electric power stations and general industrial coal users in major-dispute months during those years, although evident, appeared as a small hummock on a downward sloping seasonal hillside and suggest little more than constant maintenance of already established security positions (Chart 7). Earlier study found the pre-1940 period one when the current-transfer offset factor manifested substantial power.[7] In such periods even complete closing down of some mines can hardly generate much concern among coal consumers. Our ratio calculations now reflect this security of consumer positions.

For all three groups an entirely new pattern of coal consumption appears in 1943. New heights never experienced during any other part of the 1933-42 decade were reached and coal reserves more than kept pace with this upward surge of consumption (Charts 4, 5, and 6). One has to go back to the minor-dispute year 1942 to get the proper perspective, for all through that year the stockpile ratios continued to mount with hardly more than casual relation to the natural heat of summer (Chart 7). By December 1942, the stockpile ratios for electric power utilities and general industrials had reached the unprecedented

[7] Christenson, *op. cit.*, pp. 529-31.

figures of 364 and 280 per cent respectively. While railroads with a maintained continuously well about 100 per cent for all twelve months. earlier, they had never before closed a year when reserves had been maintained continuously well above 100 per cent for all twelve months.

The year 1943, therefore, opened with all three groups having greater shelter from interruptions in fuel deliveries than they had ever known. Moreover, although generation of electric power rose more or less continuously from month to month (Chart 4) thus diluting the seasonality for that group, both general industrials and railroads exhibited the normal seasonal amplitude (Charts 5 and 6). Hence for the major-dispute months of April, May, and June the calculated ratios of Chart 7 substantially understated the actual margin of consumer safety. However, while the high stock ratios of January were followed by their usual spring decline, there is also a suggestion of the quest for unnecessary additional safety as the ratios for all three groups rose to meet the anticipated production curtailment of June, when disputes were to account for 3.4 million man-day losses.[8]

The 1943 dispute time losses of October and November were among those identified in the more critical list earlier (p. 00). Of smaller magnitude than those of May-June, they came when the seasonal increase in coal consumption was under way. Hence the calculated ratios overstate the safety margin in October slightly and in November still more. However, this is also true for the ratios of the similar months of 1941 and 1942. While the 1943 ratios are not equal to the unprecedented ones for 1942, nevertheless, for all three groups they are distinctly in excess of comparable figures for 1941. Even in those critical end-of-the-year months of rising consumption, therefore, the impact of coal mine disputes could hardly have impaired fuel consumption for these groups. Reference to the absolute patterns of consumption and stocks shown by Charts 4, 5, and 6 seems to strengthen this conclusion drawn from the ratio calculations.

The first two years of our second decade are the high-production war year 1944, marked also by only minor-dispute time losses in coal mining, and 1945, initiating postwar reconversion. In contrast to 1944, the latter year was one of industrial recession beginning in the spring. Although 1945 time losses were sufficient to class April and May as major-dispute months, they were not of large magnitude. They represented sporadic outbursts rather than any general interruption of coal mining, and earlier study showed them having no effect on total coal production.[9]

Viewing the matter from the consumption side we see further evi-

[8] *Ibid.*, pp. 536-37.

[9] *Loc. cit.*

dence of the negligible influence of time-shift during the first half of 1945. The March, April, May ratio calculations for utilities, general industrials, and railroads show an undisturbed pattern of seasonal shrinkage (Chart 7) with no suggestion that any of these coal consumers were concerned about building up compensatory reserves as shelter against later retardation of deliveries. The continued effect upon our calculation process both of the general downward recession and of the reconversion shift of the seasonal consumption trough is the real explanation of the high October ratios rather than anticipation of possible stoppage in coal deliveries.

Added to reduced industrial consumption because of reconversion, the labor disputes outside coal mining in the last quarter of 1945 and the first months of 1946 augmented that proportion of coal mined during those months which could be directed toward reserves by freeing it from current use. Such accumulation of reserves in advance of the 1946 disputes of April and May did actually take place. While the calculated ratio for electric power utilities rose slightly in February to 288 per cent and sagged to 264 in April, those for general industrials and railroads, at 119 and 92 per cent in January, rose sharply to 208 and 157 respectively in April (Chart 7). It is certain, however, that the ratio calculations for these particular months understate the safety margin for electric utilities and also overstate it for the other two groups. No other disputes in the recorded history of bituminous coal mining involved as large time losses as those for April-May 1946, and the continuation through the second month drastically reduced reserve stocks. Thus the June ratios calculated 182, 106, and 66 per cent respectively for these three groups. These June figures, made against a deseasonalized summer line, are conservative. They seem to be the narrowest safety margins to which these three groups had ever been subjected. Even so, ratios comparable to them had occurred frequently in the past. The low June-July ratio against deseasonalized consumption can be easily observed in minor-dispute years as well (Chart 7). It appears, therefore, that even the major-dispute time losses of April-May 1946 caused no impairment of consumption patterns of these three groups.

This conclusion concerning the impact of the disputes during the first half of 1946 is still more emphatically true for the disputes of the close of that year originally identified as deserving special scrutiny. In November, when dispute man-day losses in coal were about 2.3 million man-days, freight car loadings other than coal and coke were 3.5 million cars, which was the highest November figure reached during the entire two decades. December car loadings, usually a little under those for

November, were not so striking in comparison with other years, but they were in excess of those for 1945 and matched those to come in 1947 (Chart 6). Production of electric power was held at about 24 billion kilowatt hours for each of the three months of the last quarter, a higher level than had ever before been reached (Chart 4). The calculated ratios of stocks to deseasonalized consumption, slightly under those for November and December of 1945 in the case of the electric power utilities, were above the 1945 figures in both months for the general industrials, and in the case of railroads they were distinctly above in November although slightly under for the month of December. Reviewing the record in retrospect, it is clear that the ratios were more than adequate to prevent any impairment of consumption, for in both months and for all three consumer groups they were well above the ratios effective during the year 1947 when reconstruction was completed and production had moved on to new heights. Looking over the whole of 1946, therefore, whatever else may be said about the trials of industrial reconversion, we find no evidence that hindrance of deliveries because of dispute time losses in the coal mines ever impaired consumption of these industrial market-access consumers.

The disputes of 1947 call for little attention. Of small magnitude, timed at the middle of the year, they never had the potentiality of impeding coal deliveries to the same extent as those of 1946. Consumption in 1947 was maintained at high levels and stockpile ratios were also high enough to meet consumption requirements.

The year 1948 contains mild forebodings of things to come. While industrial production indexes continued to advance over those for 1947, the advances were so slight that, toward the end of the year at least, they might have been accounted for by the always possible element of statistical error. Specifically so far as industrial coal use was concerned, growth in markets clearly had been arrested. Coal consumption by the electric utilities took an unusual downward course during the last quarter of the year, minimum monthly consumption by general industrials was reached two months earlier than usual, and railroad use exhibited a much sharper than customary spring seasonal drop not followed by the normal postsummer increase. In part, the change in railroad use may be attributed to the continued dieselization program; but more than that was involved, as freight car loadings other than coal and coke for most months of the year were noticeably under those for 1947 (Chart 6). An aspect of these changes in industrial coal use is that they again probably lead to some understatement of the electric utility ratios for the major-dispute months March and April, while overstating them for general industrials and railroads. But com-

pared with ratios for the same months in earlier years, they were clearly adequate to meet consumption requirements (Chart 7).

If the time losses of July 1948, which occur in consumer-owned steel company mines, are postponed for later examination, we come then to the major disputes of 1949-50. The larger meaning of the statement that 1948 contained forebodings of things to come now stands out sharply. July 1948 was not merely the usual midyear signal for the seasonal upswing in stockpile ratios; it was the start of the building of a mountainous accumulation that did not reach its summit until the last quarter of 1949 (Chart 7).

The 1949 episode was not, however, a duplication of the 1942-43 demonstration of the ability of the great productive power of the bituminous coal mines to more than keep pace with increasing industrial demands. It was rather a showing of the sluggishness of the mines' reaction to the continuing fall in consumers' requirements. The repeated dispute time losses during 1949, even when supplemented by the union-ordered three-day weeks of July, August, and September could not produce any shrinkage in the calculated ratios. Only the rising consumption requirements of the winter months, with substantial time losses of October 1949 and February 1950, brought the ratios down to levels comparable with those for similar months of earlier years. It is indeed true that by March 1950 the ratio of reserve held by railroads fell to 40 per cent, which was the lowest calculated for the entire twenty years. Even then it is hard to be convinced that any impairment of service took place because of lack of coal supplies, for freight car loadings (other than coal and coke) beginning at low levels in January rose noticeably both in February and again in March. A critical examination of the records for 1949-50, therefore, leads to the conclusion that the stocks of market-access industrial consumers were always adequate, and for most months much more than adequate to meet requirements.

Even though originally listed as calling for special scrutiny, the 2.1 million man-day time losses of October 1952 can now be disposed of with little more than bare recognition. Coming as they did after the steel mill dispute of June-July had facilitated increases in coal stocks during the summer, the time losses of October produce nothing more than a welcome shrinkage in these excess reserves (Chart 7).

III. *Consumption, Reserves and Direct Access*

A. *Steel as the Fourth Member of Industrial Coal Consuming Family.* Each of the three members of the coal consuming family examined thus far was found to have peculiar properties of its own. The

steel industry also, with its subsidiary partner the coke plants, requires special analysis.

Only a small part of the coal entering into manufacture of steel is used directly as mined coal. A much larger part is used after processing in coke plants. Most of this great volume of coke used in blast furnaces is produced in ovens operated by steel companies or their subsidiaries which are referred to as furnace plants. A portion, varying between 8 and 19 per cent, is purchased from independent commercial plants.

If about 15 per cent of coal used in producing coke goes outside the steel industry, then a round number estimate gives 100 million tons of coal consumed in 1953 for steel production, or 22 per cent of the total bituminous coal consumption of that year. A little less than 40 per cent of the total coal used by the steel industry is purchased from commercial markets and somewhat more than 60 per cent comes from mines operated by the steel companies or their subsidiaries.[10]

With existing technology, coking coal is indispensible in the manufacture of steel.[11] Combining steel with coke plants and locating both in close proximity to coal mines is clearly advantageous. Given these physical relationships, vertical ownership is an easy although not inevitable connecting link. Thus the steel industry becomes the major direct-access consumer.

B. *Compensatory Reserves of Steel Mills and Coke Plants.* Chart 8 is a variant of those presented earlier (Charts 4, 5, and 6) although it reproduces identically the man-day loss record. The coal consumption record, the thin continuous line, is that for by-product coke ovens only. It therefore excludes the small amount of coal processed in beehive-type ovens, and that portion of raw coal used as it comes from the mines to the steel plants. On the other hand, it does include coal used in commercial by-product ovens for production of some coke that is consumed outside the steel industry. The heavy continuous line represents the total production of steel ingots in millions of tons The reserve stock figures are shown in a series of dots at the beginning of months as in the earlier charts. However, in Chart 8 we show, not reserve stocks of coal, but rather, reserve stocks of finished coke at furnace plants. This does not include all the coke available to the steel industry, since it does not cover that portion ready for delivery from the commercial merchant plants. It has the advantage, however, of giving an indication

[10] For confirmation of these estimates the author is indebted to Mr. Harry Moses, President of the Bituminous Coal Operators Association. (Letter dated April 23, 1954)

[11] My suggestion as to limits of substitution of other coals is based on Voskuil who writes: "Only metallurgical coke can be used for reducing iron ore to the free metal" Walter H. Voskuil, *An Economic Study of Fuels in Manufacturing*, Circular Series No 63, University of Illinois (Urbana, 1952), p. 17

CHART 8. MAJOR-DISPUTE MONTH MAN-DAY LOSSES IN COAL MINES RELATED TO STEEL INGOT PRODUCTION, COKE PLANT COAL CONSUMPTION, FURNACE PLANT COKE STOCKS

not simply of raw coal reserves but of those which have already gone through the ovens and are hence ready for immediate use at the steel mills. Later, in a different way, the coal stocks held both by steel plants and those of the by-product coke ovens as preprocessed reserves will be examined.

Chart 8 shows that the tonnage of coal consumption at coke ovens corresponds very closely to steel ingot production. Usually the tonnage of coal consumption at the by-product ovens has been somewhat larger than tonnage production of steel. That this has not been true since 1949 is probably a reflection of the shrinkage in the use of coke for other purposes and of expansion in steel manufacturing.[12] It should be noted that the three greatest reductions in the level of steel production for the last ten years of our record, namely those of February 1946, October 1949 and June-July 1952,[13] were associated with disputes in the steel industry itself, rather than with stoppage of coal mining. In Chart 8 the fall of steel production associated with the dispute over steel pension plans in October 1949 also exactly overlaps the bar showing losses of 6.4 million man-days in coal mines for that month, but it does so independently, not because of the interruption in coal mining.

C. *Relation of Disputes to Stockpile Ratios: Direct-Access Consumers.* Steel mills and coke plants are not only the best illustrations of direct-access as well as of productive-use consumption, but they also possess special characteristics as to the continuity of operations. Since there is little of blending with final use, the operating pattern is only indirectly associated with temperature changes. Hence seasonal variations of consumption are moderate, and almost fade out at times. Observation of these relations was made years ago by others.

Since the work of Kuznets,[14] and Åkerman it is recognized that variations in seasonal patterns between industries may also be accompanied by deviations in these patterns from year to year. Moreover, Åkerman emphasized that deviations from regularity associated with the boom phase of the business cycle tend to be most marked in the capital-creating industries.[15] These are the very industries we have called productive-use consumers and of which the steel industry is the most nearly perfect example. Hence from this standpoint alone, we must expect the steel industry to exhibit less of security against stoppages in the mines growing out of seasonal shrinkage in demand.

Other matters also complicate our problem in the case of the steel industry. Inability to separate monthly output as well as time losses for the consumer-owned mines from the aggregate figures for all mines

[12] See U.S. Bureau of Mines, Monthly Coke Report M.C.R 311 Supplement and Feb. 5, 1954 Mineral Market Report 2186 (July 1953).

[13] The 1946 dispute stoppage in steel was from January 21 to February 15. In part concomitant with it was the dispute stoppage in the automobile industry from Nov. 22, 1945 to March 13, 1946; the steel dispute of 1949 began Sept. 30 and was settled Nov. 11, while that for 1952 extended from June 3 to July 24.

[14] *Op. cit.*, pp. 253, 338.

[15] Johan H. Åkerman, *Economic Progress and Economic Crises* (London, 1932), p. 42.

results in an underestimation of the potential current-transfer existing within the commercial sector.[16] With regard to the impact of disputes upon coal consumption in the steel industry, however, this handicap becomes still more serious for the following reasons: (1) the "captive" mines in steel have been affected by all major time losses since 1941; (2) most of the coal used in the steel industry is special-grade coking coal, available only from limited areas. Both of these factors reduce the significance of the current-transfer offset factor to very nearly zero. Hence examination of stockpile ratios for steel mills and coke plants calls for still more careful scrutiny than does reviewing the record for other consumers.

Chart 9 seems the most suitable view obtainable from the available materials. The bars showing dispute months are smaller than those of Chart 7 because of scale modifications. By lowering minimum time losses to 250,000, the September 1945 dispute which accounted for 290,000 man-days has been included. The September 1945 time losses are the only ones that do not appear in the other charts, but a distinctive shading has been used for the 1945 supervisory dispute, as well as for those of 1941 and 1948 known to have been confined to the steel companies' coal mines. All the others are shown as they appear in Chart 7 and are called general coal mine disputes. Except that actual consumption instead of the deseasonalized figures was used in case of the coke plants, ratios were calculated in the same way as in construction of Chart 7. The black dots outside the chart frame indicate omissions of ratios over 450 per cent due to the steel disputes of 1949 and 1952.

Still more so than in the earlier case, Chart 9 needs to be read with its companions, Charts 3 and 8. Since more than 80 per cent of the coal used in steel manufacturing must first go through coke ovens, the full picture of the impact of dispute time losses in coal mining upon the steel industry requires the combined examination of coal stocks at the ovens and the reserves of finished coke. The small time lag between the availability of coal at the ovens and of finished coke at the blast furnaces may be neglected. The Bureau of Mines Coke Section reports of stocks held by furnace plants, used to construct Chart 8, certainly understate the safety reserves of the steel industry since some portion of the merchant plant holding is available to steel mills. For our analysis it is these conservative estimates of coke reserves, the monthly steel ingot tonnage (Chart 8), and the coal ratio for the by-product coke ovens (Chart 9) which are considered most significant.

Putting together the observations of these three items for the period

Ratio Calculations all based on data from Weekly Coal Reports, Bureau of Mines.

CHART 9. RATIOS OF STOCKS TO COAL CONSUMPTION BY STEEL MILLS AND COKE OVENS WITH MAN-DAY LOSSES IN SOFT COAL

before 1945 yields nothing new. It is the same pattern of complete security from disturbance by coal mine disputes which has already been seen for market-access consumers. Its repetition, even with slightly different details, would prove monotonous, and raise doubts as to the merits of giving these direct-access consumers any special attention. Such doubts, however, recede as the 1945 record is examined and disappear entirely when the disputes of later years are re-examined.

Understanding of 1945 requires re-emphasis on its character as a reconversion year, and also upon the peculiar position of steel in the reconversion process. It would probably be correct to say that more than any other single industry—unless it might be aircraft manufacture—the steel industry felt the full force of reconversion. The effect was a gradual one, however, and steel production remained high during the first quarter of the year although slightly lower than during the corresponding months of 1944. The scattered time losses of April and May appear not to have disturbed steel production in any way.

The supervisory disputes of September and October were different, as they directly affected the steel-owned mines. Although September involved only 290,000 man-day losses, after spreading to other mines the recorded losses in October were over 3 million man-days. Stockpile ratios at coke ovens which, except for a few midyear months earlier and the high production war year 1944, had never been permitted to fall below 75 per cent, sagged from 78 per cent at the beginning of 1945 to barely 62 per cent by September 1 (Chart 9). The rise to 84 per cent at the beginning of October was due to a drop in coke-oven consumption for that month rather than to any augmentation of coal supplies. Thus one may surmise that a part of the reduction in steel tonnage in October 1945 was a result of the coal shortage growing out of the supervisory dispute of that month.

The first point in analyzing 1946 is that the high stockpile ratios of January and February (steel mills, January—128; coke ovens, February—139) resulted in part from the reduced coal consumption because of the steel disputes. However, the growth of absolute volume in coal stocks while the mines were working and steel plant operations were reduced drastically, was very substantial. First-of-month coal stocks at steel mills rose from 600,000 tons for January to over a million tons by April, and coke-oven coal stocks advanced from just under 5 to 8.2 million tons in the same period. The figure in both cases was the highest for that month since the banner year 1943. Applied to April deseasonalized consumption for steel mills and to the coke oven actual consumption, these stockpiles represented ratios of 130 and 148 per cent respectively, in spite of the return of steel production to 83 per cent capacity in March. Drastically reduced coal mining, because of 7.5

million man-day losses during April, left steel plants and coke ovens with approximately half as much stocks beginning on May 1 as they were holding at the close of the first quarter. But the dispute in coal continued through the second month, and May involved almost as large man-day losses as April. The May 1 stockpiles, in ratio terms, were favorable (104 in steel mills, and 115 per cent in coke plants) only because of a sharp drop in coal consumption during May with a concomitant fall in steel output to just under 4 million tons. The restoration of some mining during May was insufficient to prevent a still further reduction in stocks, and June opened with steel-mill storage under 500,000 tons and coke-oven supplies of 2.5 million, the lowest on record for the entire twenty years. Finished coke reserves at furnace plants, after climbing during the first quarter to just under a million tons, were down to less than 300,000 tons by June 1, which also represented a twenty-year minimum. All these elements suggest that the immediate impact of the disputes of April-May in 1946 brought reduction in current steel output.

However, it seems inappropriate to attribute any of the drop in steel production during November and December to coal-mine stoppages in these months. The rise in the ratios, during the last half of 1946 is reliable. If one overlooks the huge reserves on April 1, coal stocks at steel mills and ovens as well as finished coke at furnace plants, both on November 1 and again on December 1, represented almost the largest absolute tonnages held during any months of the year and were adequate to have supported a considerably larger steel output had it been called for. Probably the same can be said for the coal supplies available at midyear both in 1947 and in 1948. This was true even though the July dispute of 1948 was concentrated on steel company mines.

We cannot be so confident that shortage in coal supplies made no contribution to reduction of steel output in April of 1948. While our stockpile ratios at the beginning of both March and April were somewhat over 100 per cent, it must be remembered that steel production in the first quarter of 1948 was running at about 7.5 million tons monthly. Therefore continuing large coal supplies were essential to maintain such ratios. Moreover, although the dispute losses in the coal mines were not as large as those of early 1946 they still were over 4 million man-days in each of two months. The first of these was March, which tends to be the peak of steel production and therefore also is the month when high consumption makes accumulation of coal reserves difficult. Coal stocks at coke plants of 8.8 million tons on March 1 became 7.4 by April, and 4.3 on May 1. A part of the reduction in steel tonnage from 7.5 million in March to 6.3 in April, therefore, may have to be

charged to this shrinkage in coal supplies which grew out of the time losses in the mines during those two months.

The three months, October 1945, May 1946, and April 1948 are the only ones in the entire twenty-year record when there may be strong reasons for concluding that some impairment of coal consumption and hence of current steel production resulted from stoppages in the bituminous mines. However, even with this conclusion established it does not follow that there was a forced reduction in *total* steel tonnage if one grants the possibility of production shifts through time. As direct-access and productive users of coal, steel mills, with subsidiary coke ovens, appear as the most conservative of all industrial consumers in the maintenance of reserve stocks, except railroads. This is partly because for direct-access consumers the most economical storage is to leave coal where nature put it. The other side of the story, however, is that a productive-use consumer may have the alternative of storing coal as a semifinished product. Hence the immediate rational adjustment to anticipated interruption in supplies may be to move all available coal through the coke ovens and also perhaps augment steel ingot tonnages as well. One needs to think of a blast furnace not merely as *using up coal* but also of *putting it into* steel. The anticipatory time-shift form of the offset factor on the coal production side then becomes expanded to include advances in steel output by productive-use consumers.

However, even such advance steel production might not be adequate to provide complete protection from reduced coal supplies if disputes extend beyond a single month. But this is the very situation to which the retroactive feature of the time-shift form of the offset factor is applicable. This retroactive feature is of no significance to final-use consumers. No one would claim that large coal supplies for household heating during the mild month of May are effective compensation for having endured shortages during bitter winter months. But increased steel production in May can make up for reduced output in April especially if fabricating plants can be furnished with extra inventories.

An important element of this argument is the fact that even during boom periods, steel plants rarely operate at calculated full capacity. "Full employment" in the tremendously productive American economy does not mean continuous employment of all workers in every industry, and it is a fantasy to claim that what is not produced today cannot be produced tomorrow simply because we do not know how to measure the exact amount of tolerance.

Although we must be content with something less than conclusive proof, fortunately the record does permit a demonstration of the reasonableness of this view. If we re-examine the record for our three identified months, the following picture is revealed. Steel was at 69, 52,

and 80 per cent of capacity in October 1945, May 1946, and April 1948 respectively. For October 1945 this represented absolute output of 5.5 million tons. In spite of the fact that the supervisory dispute had already begun, the tonnage for September was almost 6 million and significantly above that for August. Moreover, after the conclusion of the dispute, the swift rebound in coal supplies and consequently in steel production made November close with steel output of almost 6.3 million tons or about 5 per cent above that for September. Had it been possible to interchange the production figure of September with that of October, the year 1945 would have shown a typical seasonal pattern with primary and secondary peaks in March and November, respectively, a main summer trough coming late, with another in December, and the whole skewed by the slow downward course of reconversion. Hence it becomes plausible to say that the supervisory disputes of 1945 did not reduce steel production at all, but perhaps they did shift the monthly timing.

The 1946 case is complicated by the fact that the dispute in the steel industry itself during January and February meant operations of 50 and 20 per cent of capacity respectively in those months. However, the output in March passed 6.3 million tons: higher than in any of the last six months in 1945 except July. Even though coal production during April came as near to a complete stoppage as it has ever done before or since, steel tonnage (5.9 million) almost reached that of March. But for reduced operations at the beginning of the year, April steel production might have been regarded simply as the spring retreat following the normal primary peak in March. It was, however, the continuation of the coal dispute through a second month that forced reliance upon the retroactive feature of the offset factor. The rapid rise of steel output following the settlement of the dispute disregarded the customary summer trough and continued upward month by month until November (Chart 8).

The contention that reduced output in April 1948 was counterbalanced by increases for other months of the year is sustained more easily. The spring 1948 coal stoppages extended through two months beginning in the middle of March and extending to the middle of April. In magnitude of time loss they were only a little more than half as large as those of 1946 and there was clear advance notice of them early in February.[17] Furnace-plant coke stocks on March 1 reached the largest absolute quantities since the closing months of 1946. In this setting the steel plants operated closer to full capacity operations during all three months of the first quarter—including the major dispute

[17] See Colston Warne, *Labor in Postwar America* (Brooklyn, 1949), pp. 384-85.

month of March—than in any other first quarter since the banner war years 1942-44. Thus the view that depletion of the large coal and coke reserves by keeping steel mills operating at 95 per cent of capacity during March amounted to creating 7.5 million tons of ingots as embodied coal is thoroughly consistent with the facts.

Not only was first-quarter production large enough to make possible tolerance of more than customary spring shrinkage in April; also the rebound after resumption of coal mining was very fast. May production was back to the March volume and all the other months for the rest of the year—including the July vacation period—showed the same kind of superiority over the corresponding months of the earlier postwar years as had been exhibited during the first quarter. Certainly this cannot be regarded as positive proof that, had there been no reduction in April output, total annual production in 1948 would not have been still larger than it was. But a more qualified conclusion does seem reasonable; reduction of steel output to 80 per cent of capacity in April was made up for in large part by operating at considerably above 90 per cent for most of the other months of the year.

A minor addendum is called for concerning the steel industry and the large time losses during 1949-50. The growing volume of furnace-plant coke reserves along with concomitant fall in coal consumption at the coke ovens during 1949 can be seen clearly in Chart 8. They furnish conclusive proof that the disputes in the coal industry could have had no responsibility whatever for falling steel production. Even the continuation of dispute time losses into 1950 would have failed to reduce huge reserves to customary levels but for the sharp increase in steel output at the turn of the year (Chart 8). There remains only a faint possibility that the large time losses of February 1950 may be assessed with some responsibility for the slight reductions in February-March steel output (7.3 million tons for each of these months) below the January level (7.8 million). If such a charge were considered seriously, reliance on the retroactive feature of the offset factor furnishes more than adequate reply; both April and May steel production reached higher levels (approximately 8.3 million in each month) than obtained during any other months in what later came to be known as the year of Korea.

IV. *The* Total Analysis: *Seasonality, Compensatory Reserves, and the Offset Factor as Consumer Shelter*

A. *Omitted Items.* This analysis covers approximately 75 per cent of the coal consumption. However, there is the possibility of some individual hardships within our separate groups which could not be identified by methods used in this study. Supplemental examination,

while yielding no conclusive evidence, suggests that allowance needs to be made for the possibility of consumer inconvenience in some individual cases.[18] Moreover, it would be a mistake to assume that the remainder of total consumption is unimportant. The omitted 25 per cent is made up of cement plants, the foreign buyers—including shipping companies—and domestic buyers purchasing through retail yards. Little information is available as a basis for estimates of the foreign buyer requirements or of reserves available to meet them. Lack of information must also restrict the conclusion about the position of the consumers who rely on retail yards. Records permit only the crudest guesses of coal accumulated in household bins during the summer and fall months. Review of estimated stocks of the retail dealers barely touches the problem. Neither do available materials permit construction of any very satisfactory seasonal index of household consumption. Simple average calculations of seasonal movement of recorded retail deliveries during the years 1942-50 show July as the trough and February as the peak months with the range from 68 to 148. Probably the actual range in household consumption is much wider than these figures suggest. In general, it is reasonable to say that since the timing of labor disputes has in the past come when requirements of final-use consumers have been falling sharply it is extremely doubtful that they have contributed to any impairment of the consumption patterns.

The cement mills represent a small group of productive-use consumers whose seasonality is definitely out of phase with other industrial patterns. This should tend to make them vulnerable to the spring interruption of deliveries. However, relative to the total demands of industrial users their requirements are small; their peak demands come when they meet with a minimum of competition for the services of the mines, and if there were small curtailments in spring cement production, the retroactive feature of the time-shift form of the offset factor would be especially applicable.

B. *The Combined Meaning of the Analysis.* Apart from the men-

[18] In response to direct inquiry, communications were received from public school officials in the following states Conn (1), Colo. (1), Ill (5), Md (2), Mich (1), Va (5), Utah (1). The replies are almost all to the effect that they have no evidence of stoppage of school service because of coal shortage The notable exception is the case of four teachers colleges in Illinois required to curtail operations during February 1950 by government order. However, the official of one of these colleges wrote: "Our situation was such that we would have had or could have obtained by paying premium prices, enough coal to have continued operations, had it not been for the Governor's order" (letter to the author dated Aug. 24, 1953). Special inquiry concerning positions of four large electric utilities indicate minor curtailment of service because of coal shortage at least in one case. "The electric service to only a few large industrial customers was curtailed to a very minor degree and for about a week in Feb 1950" (letter to author Aug. 20, 1953).

tioned omissions, this study has examined the impact which interruption in mining associated with labor disputes has had upon coal consumers over the period of two decades. Analysis of the monthly records for the entire period indicates no disturbance in consumption patterns for market-access consumers chargeable to coal mine labor disputes. This has been in part because the productive power of the bituminous coal industry has been great enough to permit reliance upon the anticipatory feature of the time-shift form of the offset factor. In part, however, it has also been due to the fact that most of the coal disputes have been synchronized with reductions in consumer requirements. Combination of these two elements insured the adequacy of compensatory reserves.

The case seems somewhat different for the steel mills, but the special character of their position does not become evident until after 1944. Prior to that year compensatory reserves were complete protection and reduced steel output could not properly be charged to lack of coal supplies. If one regards the level of current steel production for those specific major-dispute months after World War II as the critical test, there may have been cases of impaired coal consumption. Specifically they are those of April-May 1946, possibly those of March-April 1948, and more doubtfully those of September-October 1945.

However, the mere test of reduction in current steel output is insufficient. The extension of the theory of the offset factor to steel mills gives a more complete understanding of the actual impact of coal-mine labor disputes upon such consumers. A part of the compensatory reserves of such consumers is in the form of their own semifinished products. Moreover, by contributing to the creation of consumers' durable goods, they can transfer the retroactive feature of the time-shift offset factor in the coal mines to their own production. In its present form, this application of the theory of the offset factor to productive-use coal consumers cries out for further testing through a detailed examination of changes in durable goods inventories.

Although the applicability of the retroactive feature of the time-shift form of the offset factor to productive-use coal consumers is an important question, its significance in the coal disputes since World War II is limited to only a few cases. The largest reductions in steel output, also in consumption by coke ovens, have resulted from general recession forces or from labor disputes in the steel industry itself. The changes in coal consumption which occurred when there were coal mine stoppages appear as little more than mild monthly fluctuations which are only the vestigial remains of a seasonal pattern that has almost been "swallowed up" by the generally expanding output since the close of World War II.

Two main conclusions then emerge. First, compensatory reserves

have always been adequate to shelter market-access consumers. Second, even for the largest productive-use consumer such reserves have usually been adequate, but in special cases the application of the time-shift form of the offset factor furnishes rational support for the view that *total* coal consumption and therefore steel production has not been reduced.

The long route of this study has given no glimpse at the course of miners' wages. Neither has there been more than implied reference to the question of the relation of labor disputes to the price of coal and of substitute fuels. These are important parts of the economic problem of labor disputes in coal mines which require further study. But to have found the solution to one element of the problem, if indeed that has been done, has a value of its own. Moreover, it has the important collateral quality of sharpening the focus of the still unsolved elements. To use Emerson's words, "The field cannot be well seen from within the field. The astronomer must have his diameter of the earth's orbit as a base to find the parallax of any star."

SPATIAL AND LOCATIONAL ASPECTS OF METROPOLITAN LABOR MARKETS

By WILLIAM GOLDNER*

In the decade since the second world war, there has been increasing awareness of the complex internal structure of local labor markets. Stemming originally from attempts to reconcile wage theory concepts of equilibrium with empirical findings of wage rate diversity, the notion that "noncompeting" groups face barriers to employment other than the limits set by workers' occupations has been widely studied. The attempts to identify these submarkets within the over-all structure of the labor market have been partially successful. An extensive series of labor mobility studies has accumulated and in many of these analyses, empirical data support the hypothesis that immobilities have occupational, industrial, geographical, and other socio-economic bases.[1]

Although these findings pervade all studies, in most cases the link between the empirical results and wage theory has been far from explicit. In addition, much more attention has been paid to occupational, industrial, and interarea mobilities and immobilities than has been focused on intraarea spatial barriers. The internal geographical arrangements of the labor market complement and reinforce the occupational and industrial boundaries that have been found to exist in local labor markets. The primary purpose of this paper is to point out the significance and implications of this neglected source of labor immobility.

This paper serves a second purpose, and it comes as a joint product of the analysis, by defining in clear detail the nature of labor market boundaries. What are the outer limits of a labor market? How ex-

* The author is assistant professor of business administration at Bowling Green State University. In this prefatory footnote, he would like to reiterate his thanks which already have been expressed verbally to M. S. Gordon, J. W. Garbarino, D. L. Foley, J. Cohen and J. E. Lulofs. They have taken time to point out many inconsistencies and oversights in the original draft.

[1] A partial list of these studies should include: C. A. Myers and W. R. Maclaurin, *The Movement of Factory Workers* (New York, 1943); L. G. Reynolds, *The Structure of Labor Markets* (New York, 1951); C. A. Myers and G. P. Schultz, *The Dynamics of a Labor Market* (New York, 1951); G. L. Palmer, *Labor Mobility in Six Cities* (New York, 1954); C. Kerr, "The Balkanization of Labor Markets," in E. W. Bakke and others, *Labor Mobility and Economic Opportunity* (New York, 1954), pp. 92-110.

tensive or how narrow are these limits in the spatial dimension? And who is responsible for their alignment?[2]

The general approach is as classical as supply and demand determining price. Generalizations which can be made about the spatial arrangements of business and commercial establishments provide the premises as to the basic locational pattern of demand for labor. Confronting these premises is another set gleaned from analysis of the spatial preferences of workingmen. The supply of labor is some function of these preferences. The reconciliation of these generalizations expresses itself in certain characteristics of the journey from home to work and results in a detailed hypothesis regarding submarkets and market boundaries.

Workers' locational preferences are not a unique and independent portion of the totality of the workers' labor-market preferences. A related set of propensities are those involving workers' choices between labor and leisure. Obviously, the patterns of locational preferences, involving the places at which the worker is willing to work, and how he gets there from his residence, also involve the time spent in the journey to work. The relation of work, commuting time, and leisure time, are therefore integrally related as elements determining the workers' preference patterns. In addition, the pervasive influence of occupational and industrial attachments in affecting and limiting the job choices that the worker is willing or able to make must be considered. The total of all factors which affects the workers' preferences in the labor market is an aggregate of many interdependent variables.

The problems of workers' locational preferences are not to be dismissed as being too complex for any logical summarization. Systematic and predictable aggregation of these preferences is evident in several empirical studies of the journey to work and these very studies are the stimulus for this elaborate hypothesis. It must also be made clear that this discussion does not involve what is commonly called geographical mobility, *i.e.*, the movement of manpower from one local labor market to another. It is primarily concerned with intramarket movement, particularly, the discernible patterns of that movement, and the consequences of these patterns to labor-market and wage-determination theory.

I. *The Model of the Urban Center*

The metropolis used as a model in this analysis is an abstraction, departing from reality in many ways. Yet, when we consider that there

[2] The empirical counterparts of these theoretical questions regarding labor market boundaries are raised in N. A. Tolles and R. L. Raimon, *Sources of Wage Information: Employer Associations* (Ithaca, 1952), pp. 289-90. The quotation from an anonymous employer association official on page 290 is a striking confirmation of the argument presented in this paper.

are underlying economic forces operating in allocating land uses, it is not surprising to find certain generally recurring elements in the spatial structure of a metropolitan area.

Actually, there are surprising regularities in the over-all layout of metropolitan communities; and observable patterns of urban growth are remarkably similar among most metropolitan centers. Metropolitan communities are usually found to have:[8]

1. *Central business districts,* in which specialized trade and service functions catering to metropolitan-wide markets are located. These functions usually are located at the focus of transportation facilities in order that access may be conveniently offered to the whole community.

2. *Light industrial and commercial districts,* near and surrounding the central business district. Warehouses, garages, manufacturers of style goods and products of small bulk are typical of this category. For industries in this category, such as clothing manufacturing and printing, labor is a more important localizing influence than raw materials. Therefore, these industries cluster near the focus of transportation and compete for space with the older residences near the core of the city, resulting in hybrid industrial-residential areas.

3. *Special industrial districts,* almost exclusively devoted to products of medium to large bulk, and therefore situated in close proximity to water, rail, or highway transportation facilities. These areas are the sectorizing influences that frequently are situated not too far from the central core of a community, customarily on the opposite side of the railroad terminals or waterfront from the central business district. Sometimes this area becomes an industrial enclave as community growth engulfs and surrounds the industrial district.

4. *Large primary processing plants,* also located along water frontage, railroad lines, and highways, but farther out along the transportation network. Oil refineries and steel mills are typical of this type of establishment, with requirements for a large volume of bulk movements, substantial quantities of skilled and unskilled labor, large areas for plant, and a buffer zone between plant and community to dissipate smoke, noxious odors, and noise.

5. *Large modern assembly-line factory areas,* also located on transportation facilities, and oriented to large tracts of flat land for single-story continuous-flow assembly operations. Examples are aircraft, auto-

[8] The classification which follows constitutes a regrouping and synthesis of the discussion in E. M. Hoover, *The Location of Economic Activity* (New York, 1948), pp. 116-41. See, in addition, D. J. Bogue, *Population Growth in Standard Metropolitan Areas, 1900-1950,* (Washington, 1953), pp. 18-19 and *passim,* and D. L. Foley, "Urban Daytime Population: A Field for Demographic-Ecological Analysis," *Social Forces,* May 1954, LII, 324-25, for well-documented insights into metropolitan locational patterns.

mobile, and electrical equipment industries. These large plants are the sparks igniting the nucleation of decentralized factory areas surrounded by residential suburbs.

6. *Convenience goods establishments and neighborhood shopping centers,* distributed at important intersections and along principal streets in all parts of the city approximately in proportion to sidewalk and vehicular traffic. Examples are food markets, variety stores, motion-picture theatres, eating places, pressing and cleaning shops.

7. *Residential areas* of several kinds. Near the central business district and competing for space with light industry is the decaying core of the older residential area. Land being valuable because of the competition of commercial uses, the high property valuations lead to use of old residences as multiple dwelling units, with low unit and high aggregate return. The modern residential sections are farther out, spaced between but not too close to commercial sectors that radiate out from the central district. The newest residential areas are on the periphery and also may be adjacent to or near large but clean industrial plants of the type described in 5.

This generalized ordering of urban spatial relationships suggests that there are systematic influences that affect labor supply and labor demand operating out of the identical forces that array the spatial relationships themselves. The particular spacing of establishments on the basis of the convenience of bulk transfer suggests that industries, another way of naming or specifying products or groups of products, are a particularly important differentiating factor on the labor-demand side. Similarly, the clustering of homogeneous types of residences in neighborhoods and districts of the metropolis suggests that certain systematic uniformities, such as those based on income, occupation, and perhaps industrial attachment, prevail on the labor-supply side of the market. A more detailed inspection of these grouping and associative tendencies follows.

II. *The Locational Aspects of Labor Supply in Metropolitan Labor Markets*

A summarizing concept which aids in describing the patterns of workers' locational preferences is the "normal preference area." The normal preference area of an individual wage earner is that geographical area within which he is willing to work at a particular point in time. This area is normal in the sense that it is associated with the worker's normal or regular occupation, compensated for at the normally prevailing or average rate of pay, and assumes the general level of economic activity is at some normative level. In abstracting from variations in pay level, in working conditions, in nonpecuniary job amenities,

and in other factors associated with workers' selections of jobs, the slighting of these items is not meant to diminish their importance. As has already been mentioned, workers' locational preferences are only a partial explanation of the whole complex of workers' preferences and the factors which have been discounted have their proper place in the constellation of preferences. Later, factors influencing the scope and extent of the normal preference area will be considered.

The normal preference area may have a circular shape, it may be elongated if, for example, the transportation network makes certain axes of the preference area equal in time rather than distance, or it may be highly irregular reflecting idiosyncracies of the worker, or irregularities in topography, or other frictions.

Some elemental characteristics of workers' locational preferences can be seen in a highly abstract model. Let us assume completely undifferentiated units of manpower, each carrying with itself the appropriate mixture of capital and other inputs necessary to produce a unit of homogeneous output. Assume further that these units of labor are spread with equal density throughout a circular urbanized area. In this highly simplified situation, which is intended to abstract from the journey to work, work places and residences are uniformily spread throughout the labor market in the most unspecialized form, and no rational locational preferences may be said to exist. Each worker can produce the economic product where he is situated.

Let us now drop the assumption of occupational homogeneity, but still posit that work places are distributed equally throughout the area. Under this set of assumptions, small teams of complementary occupations would have to form to produce the homogeneous product, their work places very close to their residences. Residential districts would be occupationally heterogeneous, and by assumption, commercial and business establishments would show no tendency to cluster. The teams of manpower that cluster together for production purposes would have to be larger, the greater the degree of occupational specialization. Also, the larger these teams, the larger the average distance to work from the equally dense residences to the equally spaced work places.

Let us now enlarge the size of the team at each work place and see what happens. If the degree of occupational specialization is such that teams must have 25 workers to be complete, then perhaps all the workers on both sides of a city block would have to assemble in the middle of the block to carry on their production. If 250 workers are required, then workers would have to assemble at a central work place from all of the residences in perhaps four square blocks. And if 2,500 workers were required the area from which they would have to come might cover a square mile. We must recall that work places of the

same size are springing up throughout the area but it has been postulated that they are equally spaced and of the same degree of desirability, so that there are no rational alternatives. As the sizes of work places are increased, the average length of journey to work increases, and somewhere in this process, first one and then cumulatively more workers will find the progressively longer journey to work burdensome. The points at which these crystallizations of dissatisfaction take place define the boundaries of the particular worker's normal preference area.

Before we return to the concrete generalizations of metropolitan locational structure which were previously discussed, it is necessary to work out one more concept, the aggregation of normal preference areas. Chart 1 will be helpful in clarifying the aggregation procedure.

Workers in a metropolis have normal preference areas like those outlined in Chart 1.1. Because of the heterogeneity of preferences there would be much overlapping. This can be seen along a specific axis *aa* as shown in Chart 1.2. Not all points on axis *aa* fall within the preference areas of the four workers on the map, and each of the workers is available only along a short range of *aa*. The aggregate number of workers available at points along *aa* can be determined by summing the individual preference ranges along *aa* as shown in the preference profile in Chart 1.3. The four workers are available only for a short range *rr′* on the axis *aa*. Less than four workers are available as we move toward the extremes of the axis. These preference profiles are perfectly generalizable because the line *aa* can be drawn through the mass of preference areas in any direction and through any selected point.[4]

Now that the mechanics of aggregation have been explained, let us turn to the simplified models which we have previously discussed in order to determine the typical cross-section patterns. If individual preference areas vary unsystematically throughout, say, a circular urban area and occupational differentiation does not exist, then the aggregation of preference areas would result in a virtually flat preference profile along any axis of the area, with the frequencies declining at the periphery. The edge of the labor market defined in terms of workers' preference areas would be beyond the perimeter of residences out to the limits of the outermost worker's preference area. It is noteworthy that this boundary would be at the end of a gradient, *i.e.*, there would be decreasing frequencies of workers available as we move out from the area-wide flat plateau of aggregated preference areas to the edge of the outermost preference area. The boundary of the labor market

[4] The gradient pattern of the preference profile has been confirmed in empirical work by J. D. Carroll, Jr., "The Relation of Homes to Work Places and the Spatial Patterns of Cities," *Social Forces*, March 1952, XXX, 276; and L. F. Schnore, "The Separation of Home and Work: A Problem for Human Ecology," *Social Forces*, May 1954, XXXII, 338.
CHART 1. AGGREGATION OF WORKERS' LOCATIONAL PREFERENCE AREAS

is therefore a function of workers' locational preferences—of how far they are willing to go—in addition to the physical limits of the urban area.

If we drop the assumption of occupational homogeneity, but assume that each occupational skill is scattered randomly throughout the area,

then the preference profiles would still be flat across the whole of the area, with a tapering gradient at the boundaries. This is true by simple addition, for we could treat each occupation as a homogeneous factor, with results already described. The addition of flat frequencies across the whole area would result in a flat aggregate. In this model, a work place would have available to it a number of workers, occupationally diversified, equal to the cumulative frequency of the normal preference areas that have in common the point where the work place is located. A preference profile along any axis passing through the work place location would measure the number of workers on which that establishment could draw. And if all work places were the same size and equally spaced, the whole labor supply could work without any wage-earner working outside his normal preference area. Spacing and size of firms would be a function of the density of workers' residences and the randomness of workers' locational preferences.

Let us define locational compatibility as that situation in which the aggregation of manpower demanded by the firms in the labor market does not exceed the market preference profile at any point. If we may change the object of the traditional game of the county fair gambler, we are seeking the largest pea that will fit snugly under the walnut shell. Such a labor market under our previous assumptions, would consist of a galaxy of establishments of equal size, spaced equally throughout the area, each plant drawing upon the nearby labor supply to the extent that no worker has to go beyond his normal preference area. The size of each firm, and of all firms under our assumptions, could increase up to that point where one or more workers would have to be drawn beyond his normal preference area. In this highly artificial situation, the maximum size of firm is subject to the restriction imposed by workers' locational preferences.

The locational compatability which has just been described is in no sense a self-adjusting equilibrium toward which all establishment sizes must adjust. It merely defines the degree of adjustment of the aggregate workers' preferences on the supply side of the labor market with the aggregation of employment opportunities on the demand side. Work places may be smaller in size and therefore not test the limits of the workers' preference areas, or they may be very large and require at least some workers to work beyond their normal preference areas. Although the availability of labor does affect the size of establishments and shortages of labor may constitute a restraint on establishment size, other determinants of the size of firm are equally or more important. Factors influencing the size of firm are therefore considered to be exogenous to this model.

III. *Factors Associated with the Scope and Extent of the Normal Preference Area*

So far we have assumed that normal preference areas, although not necessarily uniform, varied in no systematic way, so that in aggregating them, a uniform frequency of workers was available at all points in the urban area. We will now introduce some variants which logically qualify this assumption.

Normal preference areas conveniently reflect several labor force participation concepts, and therefore make it possible to assimilate into our model important features of labor force dynamics. For instance, the entry into the labor market of a person who has heretofore been outside the market is reflected in an additional normal preference area being included in the market aggregate. In like fashion, workers who traditionally enter the market during particular times of the year for seasonal work may project very narrow preference boundaries during the off season, a situation reflecting the fact that they would take a job then only under special locational conditions.

Cyclical fluctuations of the economy likewise reflect themselves in the expansion and contraction of the normal preference areas. Normal (as distinguished from supernormal) full employment peaks are reflected by smaller preference areas in two ways. First, the greater availability of job opportunities is matched by the individual worker's increased expectation of finding one among the many available nearer his home. Second, the expansion of particular industries generates higher wage levels in these industries, and the coexistence of abundant job opportunities and a higher pay scale may induce workers to extend their job horizon only slightly or not at all beyond their normal preference areas. For normal pay levels, the preference area must therefore be smaller. The inverse of these two conditions during periods of unemployment leads to more extensive preference areas.

Differences in the scope of normal preference areas probably exist between men and women workers, and between workers of different ages. Persons who are employed probably have narrower normal preference areas than those seeking work.

One important factor upon which there is empirical information, although only of fragmentary and suggestive kind, is the locational effect of occupation. A study of the journey to work, made in Chicago, shows that "the degree of work-residence separation increases as the level of occupation rises. . ."[5] Current weekly earnings, a variable that is highly

[5] Chicago Community Survey, "Degree of Work-Residence Separation for Wage and Salary Workers: Chicago, 1950-1951," Urban Analysis Report Number 17 (Chicago, 1953), p. 7.

correlated with occupation, shows a similar relationship, being associated positively with the distance from home to work.[6] A similar conclusion regarding the relationship between occupational level and the distance from home to work can be arrived at, for cruder occupational groups, from a study of Los Angeles.[7]

These findings suggest that workers' normal preference areas increase in scope as they move up the scale of occupations. Babysitters seek their jobs in the neighborhoods near their homes. Unskilled workers, being unspecialized, are more likely to encounter an acceptable job nearer to where they live. Skilled workers have to work for employers using their specialized skills among a far-flung group of establishments. Atomic physicists generally do not have cyclotrons near their houses although it is possible that they can better afford to move to or near their work locations.

The influence of methods of transportation on the scope and extent of normal preference areas also must be considered. The journey to work is compounded of factors integrating time, distance, transportation costs, and convenience into a complex set of disutilities. Fast, convenient, inexpensive public transportation is conducive to more extensive preference areas. If the transportation network is slow or uncomfortable, the preference areas may contract. Furthermore, if there are places out of contact with the means of transportation, dead spots within the normal preference area may arise. Most important are changing fashions in means of transportation, particularly with regard to the automobile.[8] Increasing proportions of the work-force are using individual cars to drive to work. This provides much greater variability of work-residence transport routes, and also may be faster and more convenient, although it may not be cheaper. Certainly, the use of the automobile is the culmination of a trend which has been operating for at least a half century toward faster, more flexible, more variable, more comfortable transportation between home and work. The concomitant result for our analysis is a secular broadening of many normal preference areas.

Finally, and perhaps most important, is the influence of union rules on normal preference areas. Union rules may affect the worker's normal preference area directly or indirectly.[9] Although there are varia-

[6] *Ibid.*, p. 10.

[7] E. Shevky and M. Williams, *The Social Areas of Los Angeles* (Berkeley, 1949), 172 pp. A simultaneous scanning of Fig. 9, facing page 36, which shows the locations of industrial and residential districts in Los Angeles and Fig. 11, facing page 40, which shows the predominant occupational group in each census tract, provides a striking reinforcement of the relationships mentioned here.

[8] Bogue, *op. cit.*, p. 18.

[9] The complexities of this problem of institutional influences on the boundaries of labor markets and submarkets is authoritatively discussed in Kerr, *op. cit.*

tions and complexities, craft unions, particularly those of the building trades, foster a uniformity among preference areas for all who are admitted to membership. In some cases, this may be accomplished by making membership more difficult to achieve for workers from outside a specified city or county or district. Sometimes, the normal preference area is formalized by the provision for premium pay for work outside a specified geographical area such as a city or county or an area over which the union has exclusive jurisdiction. But it is logical to assume that the satisfaction of preference for the craft union member is taken into consideration in the setting of the union wage rate. Not many or any union members will find their normal locational preferences in conflict with the bargained wage level.

In addition to the systematic influences on normal preference areas from labor-force participation, seasonal and cyclical factors, occupations, methods of transportation, and union rules, there are the non-normative influences on the normal preference area. A worker will extend the boundaries of his preference area if the pay is exceptionally favorable, or if the occupation has high status, opportunities for advancement, or other special attractions. The exigencies of wartime and the pressures stemming from that abnormal psychological environment may also lead to broadening of preference areas without regard for the influences normally resulting from full employment which have been described above. But, in the main, and particularly for industrial wage earners, the normal preference area is fairly invariable for a worker who has mastered a particular set of occupational characteristics for which he has an expectation regarding the appropriate rate of pay, during a period of economic stability.

IV. *Locational Incompatibility in the Labor Market*

We are now ready to examine the pattern which results from the weaving together of the threads of the preceding argument. From the abstract and summarized description of an urban center, we will try to generalize the contours which reflect the spatial pattern of aggregate demand for labor. From the patterns of residences are obtained summarizing premises regarding the home location of the labor supply, and from the theorizing about normal preference areas is obtained the logic of their interrelationship.

In trying to summarize the spatial organization of labor demand, it is fortunate that we are not confronted with the preference areas of particular firms. The location of the firm's labor demand is at the factory entrance and, therefore, the locational distribution of commercial and industrial establishments defines the spatial pattern of labor demand. By analogue to our preference profiles, we can form the

shape and cross-sections of labor demand along specified axes. Across the whole area of the city are neighborhood clusters of decentralized special-service areas. This layer of labor demand is roughly proportional to the neighborhood volume of local traffic.

Along the main thoroughfares, arteries, highways, and railway lines pointing toward the core of the city are strings of business firms, which, superimposed upon the nearly flat shape of the aggregate demand from decentralized services, create ridges of demand, like the arms of a starfish, in some radial arrangement. As we approach the core of the city, the increasing number of light industries raises the demand contours, and when we incorporate the extraordinarily high concentration of business firms in the central business district, we have a demand mound.[10] The mound has a marked peak at the central business district, surrounded by the declining demand profile of the central business district periphery, and finally branching out into several radial arms, all superimposed on a roughly flat (if anything, it would tend to peak at the center, too) base of generalized neighborhood labor demand.

We also have to incorporate into this structure those special decentralized nuclei of large plants or clusters of plants on the radial arms or near them, which would reflect themselves on the demand mound as subpeaks of demand.

Piecing together the elements of the labor supply mound constitutes a difficult but not insuperable problem. Keeping in mind that the preference areas of low-skill workers are not as extensive as those of higher skills, we find that the lower skills are also concentrated closer to the center of the urban area than are the higher skills. The combined effect of these factors creates a peak at and near the central business district and a fairly sharp decline in the preference profiles as we go toward the area perimeter. Those occupations which reside near the periphery of the area being of higher skills have wider preference areas, extending all the way across the central district and perhaps across to the other side of the city. But the clustering effect of narrow preference areas among workers of low skill, and the concentration of these workers in older residential districts nearer to the center of town creates a peak in the labor supply at the central area with diminishing availability as we go toward the outskirts of the community. If the business and commercial radials are also bordered by workers' residential districts, then the aggregate supply mound will have rounded branches radiating from the center.

In a compactly distributed city of small or medium size, it is probable that the aggregate of employments can be filled without violating the boundaries of workers' normal preference areas. Individual firms will

[10] Specific data suggestive of this concept are graphed in Carroll, *op. cit.*, p. 276.

fill their labor requirements with those workers who find the firm within their normal preference areas. The nonnormative influences mentioned at the end of Section III above will not have to be brought to bear in order to effect fairly rational adjustments between the locations of the labor supply and the labor demands. The problems of labor recruitment for plant personnel offices in such communities will not be particularly difficult to solve.

For larger and more sprawling urban communities, the residential concentration of low skills generates abundance of supply in some locations and deficiency of supply in other places, when consideration is given to locational preferences.[11] The deficiencies of labor supply can most clearly be visualized at the central business district and, in some cases, at the periphery of the metropolis. The deficiency in the downtown center is the result of the extreme concentration of metropolitan services with their large and intensified demand for labor measured against a labor supply curtailed by the workers' locational preferences for jobs farther out from the center of the city. On the outskirts of the metropolis, individual plants and business centers may mushroom in size, exerting a need for manpower that exceeds the thinly distributed labor supply nearby. Furthermore, the peripheral locations of the plants may lie beyond the bulk of the preference-area boundaries of workers who live closer to the center of the community.

Abundance of labor may occur in areas surrounding the central business district and along the industrial and commercial radials leading out of the city's center, primarily because of the concentration of workers' residential quarters in the less expensive and often decaying areas immediately adjoining the industrial districts and commercial sectors.

The problem of plant labor-force recruitment under these varied conditions becomes more difficult, and intensive efforts to attract workers might have to be made. The increasing distances created by the enlargement of the city, and the necessity of large plants to tap ever-widening sources of labor supply are two variables which run counter to workers' locational preferences. Thus, plant size and city size are the primary determinants of locational incompatability.

V. *Implications*

The consequences of the lack of compatability between labor supply and labor demand, when the workers' locational preferences are con-

[11] Although his analysis does not incorporate the concept of normal preference areas, the excess of jobs at the central core of the community is observed by Carroll, *op. cit.*, p 280, as follows: "Job density . . . will be expected to show a . . . declining density with distance from the center. However, we may expect greater central concentration and a more rapid decline in density than in the case of residential distribution."

sidered, are several. The key factors operating in those situations in which workers' locational preferences tend to be incompatible are large plants and large-size urban centers. To adapt to this incompatability, higher plant wage levels act to broaden the workers' preference area and therefore draw workers beyond the limits of their normal locational preferences. In theoretical terms, this means that labor supply curves to firms subject to locational disequilibrium would be relatively less elastic beyond a certain point. Small and medium-size communities with compatible distributions of industrial and commercial establishments of moderate size may operate within the limits of the locational compatability which has been described, and no pressures (via wage differentials) to force the broadening of workers' normal preference areas may exist. Such communities may have relatively little wage dispersion for given skills and the aggregate wage level would not be subject to the special influences stemming from locational incompatabilities.

Large plants in small or medium-size communities may or may not create locational incompatability depending on the plants' specific locations and the relationship of plant size to the available area labor force. Dispersion of wage rates may therefore be large or small, and wage levels might be normal or higher than normal. In communities of sizes small enough that every worker's preference area covers the whole business area, and this may very well be true for compactly spaced communities of up to 200,000 population, locational preferences probably do not effectively operate to influence the labor supply curve to the firm.[12]

The conjuncture of large metropolitan centers and plants of different sizes leads to several interesting alternatives. Plants of small or medium size are in a preferred position when they are in clusters small enough not to tax the limits of the workers' preference areas that touch upon their industrial sites. It is not uncommon to find wage levels tapering off toward the outskirts of a large urban center under such circumstances. But larger decentralized clusters of small and medium-sized plants may create points of locational incompatability and employers in those plants also may have to take measures to draw workers beyond the limits of normal preference areas. Small or medium-size plants in or near the central business district are part of the aggregate labor demand of the downtown area and mav pay equivalent area wage scales, or pay slightly lower scales if differentials in worker efficiency are acceptable.

Large plants in metropolitan centers almost certainly tax the limits of the available supply of labor, taking into consideration preference areas. If these plants locate on the outskirts, their labor requirements

[12] *Cf.*, Reynolds, *op. cit.*, pp. 41-42 and 227-28.

will in most instances exceed the available work-force, and if these firms add their needs to the cumulative requirements already existent in or near the central business district, they will contribute to the already existing locational incompatability. Thus, in large metropolitan centers, wage dispersion will be greater, and average wage levels higher because of the operation of workers' locational preferences.

This analysis has applicability for industries, too, for it suggests that industries characterized by large plants may have higher average industry wage rates. The fact that the occupational wage rates in manufacturing exceed those of all other industry divisions, with the possible exception of public utilities, seems to be consistent with the significance of the establishment-size variable in this analysis.

A second set of implications from this analysis relates to the spatial limits of the labor market. As was described in Section II, the aggregation of workers' preference areas results in a mound which tapers off beyond the boundary of the urban area. The limits of the labor market are therefore not physical, but rather are established by the value judgments of workers. Similarly, influences which expand or contract the bounds of the workers' preference areas affect the labor market boundaries. Finally, it is likely that some normal preference areas cover every habitable area, meaning that the real limit—the point beyond which no labor is willing to go—does not exist. Labor market boundaries are therefore arbitrary, flexible, and shift with time and economic circumstance. Conceivably, there even may be normal preference areas of rural workers that overlap into the urban area. These preference areas may be of a completely different size and type from those which have been described here, but their existence also impinges on any fixed and rigid concept of labor-market boundaries.

In empirical terms the external limits of the labor market should be conceived as existing well beyond the built-up area of the city, of being subject to changing influences in time, of differing among occupational-skill levels, and of being arbitrarily determined in the sense that a few workers' preference areas will exist at and extend beyond the arbitrarily established limit.

A third consideration that stems from this analysis is that a simple count of the labor force in the whole of an arbitrarily defined labor market may be extremely misleading with regard to labor availability. This will be particularly true in large metropolitan centers, or where large plants abound. Thus, the classically deduced cautions against simple aggregation of labor demand schedules[13] must be augmented by similar warnings regarding the aggregation of labor supply.

[13] A. C. Pigou, *The Theory of Unemployment* (London, 1933), pp. 61-76; and A. C. Pigou, *Lapses from Full Employment* (London, 1945), pp. 38-56.

Fourth, the fact that normal preference areas (and other manifestations of workers' preferences) vary with occupation, merits some further examination. Most important, these findings have significant implications for wage differentials between skilled and unskilled workers. May it not be that American skill differentials, which are much wider than comparable European counterparts, reflect the peculiarly American dependence on the automobile, on the privately owned individual dwelling, and on the differing scope and extent of workers' normal preference areas. North European cities have much more mass housing and many multi-unit residences, frequently concentrated in workers' districts. In addition, the automobile has no place in the European factory worker's budget. An empirical investigation of European metropolitan patterns of workers' locational preferences might start with the hypothesis that these patterns are more uniform than their counterparts in the United States.

Finally, the pattern of workers' locational preferences offers significant implications for the organization of employment service offices. Choosing among the alternatives of establishing placement offices on an industry, occupational, or general job coverage basis is an important organizational problem. If placement offices accepted the objective of facilitating contact by job-seekers, then the offices might properly be located in or near the residential sections of the metropolitan area. The clustering tendencies of workers in residential districts would automatically provide a locational basis for occupational specialization and at the same time facilitate the mass servicing of those seeking employment. Whether these advantages outweigh other considerations in locating employment offices is beyond the scope of this paper.

ORGANIZATIONAL STRUCTURE AND PRICING BEHAVIOR IN AN OLIGOPOLISTIC MARKET

By R. M. CYERT AND J. G. MARCH*

One of the most common propositions in the literature of organization theory is that a change in organizational structure results in a change in operative organization goals.[1] To the extent that this is true, it should be possible to develop a model that specifies a meaningful relationship between significant characteristics of organizational structure and some important attributes of organizational behavior.[2]

The theory of price determination in an oligopolistic market situation is generally unsatisfactory to economists.[3] Typically, neither the level of price nor price changes can be explained. The tendency of oligopolistic firms to change price relatively infrequently in comparison with firms in competitive markets has frequently been noted.[4] While it is not maintained here that organization theory can provide the whole, or even the major answer, it is the purpose of this paper to indicate some of the ways in which such theory can be brought to bear on the problem of the price behavior of a firm in an oligopoly market.

* This paper is based in part on work done under a grant made to the Carnegie Institute of Technology by the Ford Foundation for the study of organization theory. The authors, who are, respectively, assistant professor of economics and senior research fellow in administration at the Carnegie Institute of Technology, Pittsburgh, wish to express their thanks to their colleagues on the faculty of the Graduate School of Industrial Administration and to Professor James W. Fesler for their helpful comments on an earlier draft

[1] See, for example, E. Dale, *Planning and Developing the Company Organization Structure*, A.M.A. Research Report No. 20 (New York, 1952), pp. 23-38; H. A Simon, D. W. Smithburg, V. A. Thompson, *Public Administration* (New York, 1950), pp. 136, 168-172. For a study of a specific example, see H. A Simon, "Birth of an Organization: The Economic Cooperation Administration," *Pub. Admin. Rev.*, Autumn 1953, XIII, 227-36.

[2] For a general discussion of the application of organizational theory to the economic theory of the firm, see A. G. Papandreou, "Some Basic Problems in the Theory of the Firm," in B. F. Haley, ed, *A Survey of Contemporary Economics*, Vol. 2 (Homewood, Illinois, 1952). The present paper may be viewed as an attempt to meet the comments of E. S Mason, *ibid*, pp. 221-22, with reference to the need for specific theoretical examples of how the addition of organization theory variables contributes to the explanation of firm behavior.

[3] See K N. Rothschild, "Price Theory and Oligopoly," *Econ. Jour.*, Sept. 1947, LVII, 299-320

[4] P. Sweezy, "Demand under Conditions of Oligopoly," *Jour. Pol. Econ.*, Aug. 1939, XLVII, 568-73. See also, G. J Stigler, "The Kinky Oligopoly Demand Curve and Rigid Prices," *Jour. Pol. Econ.*, Oct. 1947, LV, 432-49.

Since "organizational structure" and "price behavior" are ambiguous terms, they are defined in Section I. In addition, the development of the model requires the specification of a series of functional relations between organizational features and pricing behavior. This is done in Section II. In Section III, an example of two ideal-type organization models, which under our hypotheses will exhibit distinctively different price behavior, is presented, and the implications of the paper are illustrated by an application to a classical problem in economic theory. Finally, in Section IV, a program for empirical analysis is indicated.

I. *Definition of Variables*

The approach taken here should not be viewed as challenging the basic variables that have been treated as price determinants in economic theory. For firms operating in a perfectly competitive market, for example, nothing discussed in this paper has much relevance. The position taken is that the firm's perception of the market and the firm's perception of its capabilities for action are both affected by its own organizational structure. Given significantly different organizational structures, two firms facing the same external market and using the same set of variables in decision-making will exhibit substantial differences in price behavior.

Price behavior is defined in terms of three characteristics: (1) Frequency of price change is measured as the number of changes per time unit.[5] (2) Magnitude of price change is measured for any given change by the ratio of the amount of change (*i.e.*, the absolute difference between the old and the new prices) to the old price. (3) Direction of price change can be positive or negative, measured with respect to the last previous price.

Organization structure is defined in terms of two characteristics:

1. The communication pattern of the organization. Pricing decisions are assumed to be based upon expectations concerning future sales, costs, and competitors' behavior. One of the functions of the organization of the firm is to provide information upon which such expectations can be based, and the design of informational channels by means of which such information reaches the decision-makers comprises the communication pattern of the firm.[6]

[5] In the present analysis, the primary interest is in the organizational effect on price behavior of firms operating in the same market. The restriction to firms operating in the same market is made in order to hold constant the restraints imposed by market forces upon the frequency of price changes. Since the stringency of such restraints varies from one market to another, a comparison across markets of the organizational effect upon frequency of price change could not be made without the introduction of some concept of "opportunities for change."

[6] Obviously, the relevant communication channels are those actually in use—not neces-

Primary interest is in the relay points in a communication chain. A relay point is a "message center" which receives, decodes, encodes, and then retransmits an item of information.[7] Relay points can be distinguished by the number of major variables (*e.g.*, cost) about which they transmit information. This distinction is hypothesized to have important consequences for the amount of bias introduced at a particular relay point. Bias is defined to occur if any information is eliminated, modified, or added before a message is retransmitted. The character of control over a relay point is hypothesized to be decisive for the direction of the bias introduced, as is indicated more explicitly below.

The communication pattern of the organization is described by the nature of four different communication chains within the organization: the communication chains for demand information, for cost information, for information on competitors' behavior, and for information on firm policy. The nature of a given communication chain is determined by (a) the number of relay points in the chain, (b) their character, and (c) their order. The number of relay points in a communication chain is represented by a nonnegative integer. The character of a relay point is determined by the type of information transmitted through it. If a relay point transmits only one type of information, it is defined to have the characteristic of that information. If information relating to more than one variable is transmitted by a relay point, the character of the relay point is determined by the relative frequency over time of incoming communications concerning the different variables. Thus, if most of the messages received relate to cost information, the relay point is considered to be a "cost" relay. The ordering of relay points is specified to distinguish, for example, a communication chain for competitors' behavior in which information on competitors passes through a "demand" relay point and subsequently through a "cost" relay prior to reaching the decision-making unit from a similar chain in which the ordering of "cost" and "demand" relay points is reversed.

2. The size of the decision-making unit in the organization is measured by the number of individuals in the decision-making unit for each of whom it is correct to say that there is no more influential person in the unit. Thus, if the decision-making unit for a pricing decision is a committee of four in which two committee members are dominant over

sarily simply those specified by formal organization rules. There is no reason to believe that such insistence creates insuperable observational difficulties. See K. Davis, "A Method of Studying Communication Patterns in Organizations," *Pers. Psychol.*, Autumn 1953, VI, 301-12; A. H. Rubenstein, "Problems in the Measurement of Interpersonal Communication in an Ongoing Situation," *Sociometry*, Feb. 1953, XVI, 78-100.

[7] See C. E. Shannon, *The Mathematical Theory of Communication* (Urbana, 1949).

the other two but equal in power with respect to each other, the size of the decision-making unit is 2. The problem of identifying the distinguishing power differentials within the formal decision-making unit is susceptible to solution by the application of social-psychological techniques of influence measurement to the decision-making activities of the unit under investigation.[8] For example, one method for defining power relations that has been used successfully consists in an analysis of the remarks made during decision-making conferences.[9] The variable, therefore, is operationally defined although one should not expect the analysis in any given case to be simple. Under certain conditions, distinctive pricing consequences are seen as arising from critical differences in the size of the decision-making unit. These hypotheses are found below.

II. *Functional Relations*

Demand, cost, and competitors' behavior have been the standard variables of most oligopoly models since Cournot. This paper makes no attempt to deviate from that tradition. On the contrary, the goal is to augment oligopoly theory by introducing into it some fundamental propositions of the theory of organizational behavior. Two modifications of traditional oligopoly models are suggested by such theory.The first is recognition of the fact that the values of the relevant variables actually used within the firm for establishing price are functions both of data drawn from the real world and of the organizational structure through which those data are transmitted to the decision-making unit; the second is similar recognition of the fact that the method by which perceived information on the relevant variables is translated into pricing decisions is a function of the decision-making unit's perception of, and adherence to, official firm policy.

Official firm policy, in the sense in which it is used here, consists in a specific set of constraints placed by the holders of legitimate authority in the firm upon the pursuit of organizational goals by their subordinates. A series of hypotheses with respect to the relative dependence of a pricing decision upon official firm policy, given the size of the decision-making unit, is made. The mechanisms involved are also specified.

1. Decisions by a group will, in general, be more dependent upon firm policy than will decisions by an individual. The proposition is deduced

[8] For some examples of influence measures, see C. I. Hovland, I. L. Janis, H. H. Kelley, *Communication and Persuasion* (New Haven, 1953); R. Lippitt, N. Polansky, S. Rosen, "The Dynamics of Power," *Human Rel.*, Feb. 1952, V, 37-64.

[9] J. G. March, "Husband-Wife Interaction over Political Issues," *Pub. Opinion Quart.*, Winter, 1953-4, XVII, 461-70; T. M. Mills, "Power Relations in Three-Person Groups," *Am. Soc. Rev.*, Aug. 1953, XVIII, 351-57; F. L. Strodtbeck, "Husband-Wife Interaction over Revealed Differences," *Am. Soc. Rev.*, Aug. 1951, XVI, 468-73.

from the theory of group norms and reference-group behavior.[10] There is a reasonable amount of evidence to support the prediction that an individual with an attitude at variance with his perception of the group's attitude will tend (according to the relevance of the group for the satisfaction of individual goals) to adjust his "public" position to conform to the position he expects the group to take.[11] Such behavior may be exhibited even in the limiting case where all members hold a position at variance with their common perceptions of the group standard.[12] Thus, even if every member of the decision-making group is "cost-minded," if each believes all of the others to be "sales-minded," the decision will tend to be a sales-minded one. Since in the absence of contradictory evidence, each member of the group can be assumed to believe all other members of the group to be in agreement with firm policy, the operation of group norms serves to enforce conformity to that policy.

From this it should be clear that when a relationship is predicted between the size of the decision-making unit and the extent to which decisions will be independent of official firm policy, the assumption is made that reference groups (*e.g.*, Board of Directors, professional associations) other than the pricing unit itself can be ignored. Such an assumption is based on a prediction that all decision-making units, whether composed of an individual or a group, will be subject to the same outside pressures; but only the members of a group unit will have the additional pressure of internal group norms.[13]

2. If a decision contrary to firm policy is reached by a decision-making unit, it will be more stable if made by a group than if made by an individual. This follows from the premises of the preceding hy-

[10] A reference group for a given individual consists in those other individuals with whom he perceives himself sharing common evaluative criteria for judging an attitudinal position. The literature on reference-group theory is fairly extensive For example, see T. M. Newcomb, *Social Psychology* (New York, 1950), Ch 14, pp. 220-32; R. K. Merton and A. S. Kitt, "Contributions to the Theory of Reference Group Behavior" in Merton and P. F. Lazarsfeld, eds, *Continuities in Social Research, Studies in the Scope and Method of "The American Soldier"* (Glencoe, 1950). The theory of group norms is less well developed. See S. A. Stouffer, "An Analysis of Conflicting Social Norms," *Am. Soc. Rev.*, Dec. 1949, XIV, 707-17; J. G. March, "Group Norms and the Active Minority," *Am. Soc. Rev.*, Dec. 1954, XIX, No. 6.

[11] For example, see R. L. Gorden, "Interaction Between Attitude and the Definition of the Situation in the Expression of Opinion," *Am Soc. Rev.*, Feb. 1952, XVII, 50-58; M. Sherif, "A Study of Some Social Factors in Perception," *Archiv. Psychol.* (1935), No. 187.

[12] On this point, see H A. Simon, "Notes on the Observation and Measurement of Political Power," *Jour. Pol.*, Nov. 1953, XV, 500-516, esp. 510-11.

[13] Otherwise, it might be argued that where a pricing decision is made by a single individual, he will act with the originators of firm policy as a referent, and that, therefore, the test of the mechanism posited here would be vitiated by this restraint upon his "independence."

pothesis. A group provides the individual with a defense against outside pressures and simultaneously exerts a pressure toward intragroup conformity upon him.[14] The group will ordinarily be less effective in enforcing a "revolutionary" decision than in enforcing an "ideologically sound" decision. This stems from the prediction that the latter type of decision will ordinarily create fewer cross-pressures than the former.[15]

With respect to the communication-structure variable, two hypotheses of perceptual bias are made:

1. As the length of the communication chain is increased, factors are introduced that have the effect of inhibiting change. The temporal bias introduced by the change in conditions during the interval from the original transmission of the information to its final receipt by the decision-making unit is represented as a function of the number of relay points through which the information must pass. Clearly, this is only an approximation. The significance of variations in transmission speed among the relay points (*e.g.*, cost data travels more rapidly through cost channels than through demand channels) is neither denied nor introduced into the system, except implicitly in the statement of the second bias below.

The consequences of the temporal bias for the frequency of price adjustments stem both from the fact that one never "catches up" with current information and also from the attempts of members of the organization to adjust for the bias by means of forecasts (*e.g.*, "What will the situation be by the time this information reaches the decision-maker?"). It is hypothesized that both major consequences of the time-lag in communication serve to introduce into the premises of the pricing decision a bias against change. Note that this bias operates not only in the communication of, for example, cost information upward but also in the communication of firm-policy information downward.

2. The character of the communication chain introduces a bias into the information transmitted to the decision-making unit. The form of the bias is a tendency for a relay point to de-emphasize information inconsistent with the information with which it is primarily concerned. For example, let us make the assumption that the size of the market is consistently overestimated by sales departments and costs are consistently overestimated by accounting departments.[16] Let us further

[14] For a general introduction to the study of group pressures, see L. Festinger, S. Schachter, K. Back, *Social Pressures in Informal Groups* (New York, 1950); D. Cartwright and A. Zander, *Group Dynamics: Research and Theory* (Evanston, 1953), Part 3.

[15] For discussions of the consequences of cross-pressures, see L. M. Killian, "The Significance of Multiple-Group Membership in Disaster," *Am. Jour. Soc.*, Jan. 1952, LVII, 309-14; L. Festinger, "The Role of Group Belongingness in a Voting Situation," *Human Rel.*, Nov. 1947, I, 154-80; A. H. Leighton, *The Governing of Men* (Princeton, 1945).

[16] See C. C. Saxton, *The Economics of Price Determination* (London, 1942), p. 148.

assume that overestimation of demand results in an aggressive price policy (*i.e.*, frequent price changes, price-leadership), overestimation of cost in a passive price policy (*i.e.*, infrequent changes, price-following). Under these assumptions, the firm's reaction to the behavior of others will be related to the number of biasing relay points through which cost data must pass relative to the number for demand data. In particular, it is predicted that the communication of demand data through a cost relay point will tend to produce a passive price policy, and the communication of cost data through a demand relay point an aggressive price policy. Similar deductions can be made with reference to communications downward regarding firm policy.

If the organization is stable, it is expected that the biasing of information will be reinforced by a learning phenomenon, resulting in a gradual lowering of the level in the communication hierarchy at which consistently suppressed information is filtered out of the communicated message. Thus, for example, if a given relay point has been transmitting information on the potential market but finds that this information is never retransmitted by the next relay point, and if there are no alternative channels of communication, the transmission of information on the potential market will tend to cease at the lower level.

III. *Two Extreme Models*

It is now possible to present two models that arise as antitheses from the propositions advanced above:[17]

1. A model of a firm in which price changes tend to be infrequent and reaction to competitors primarily passive might have the following organizational characteristics: (a) Price is determined by a committee of equals. (b) Communication chains between the decision-making unit and the primary sources of information are long (both upward and downward). (c) The unit making the actual price decisions does not have the responsibility for establishing the criteria for price decisions (*i.e.*, the decision-making unit is decentralized and is subject to dicta from above with respect to price policy). (d) Demand information is channeled through a cost relay point. (e) Firm policy information is channeled through a cost relay point. (f) Information on competitors is channeled through a cost relay point.

2. A model of a firm in which price changes tend to be frequent and reaction to competitors tends to take the form of price-leadership might have the following organizational characteristics: (a) Price is determined by an individual. (b) Communication chains between the decision-making unit and the primary sources of information are short

[17] It should be clear that these are only two out of a large number of permutations and combinations of organizational features that might be defined.

(both upward and downward). (c) The decision-maker for specific price decisions also has the responsibility for establishing the criteria for price decisions (*i.e.*, the decision-making unit is centralized). (d) Cost information is channeled through a demand relay point. (e) Firm policy information is channeled through a demand relay point.[18] (f) Information on competitors is channeled through a demand relay point.

In order to make explicit the implications found here for the analysis of the behavior of the firm, consider the predicted behavior in a classic duopoly situation of firms possessing the characteristics listed above. The Cournot duopoly model is taken for purposes of illustration.[19]

Let there be two duopolists in the market. Assume that Firm 1 has the organizational characteristics of the first model above, Firm 2 the organizational characteristics of the second model above. Following Cournot, let there be no costs.

The market demand function is defined to be:

$$p = 25 - \frac{x_1 + x_2}{3}$$

where p = price
x_1 = output of Firm 1
x_2 = output of Firm 2

It is further specified that each duopolist expects no reaction on the part of the other in response to a change in output:

$$\frac{dx_1}{dx_2} = \frac{dx_2}{dx_1} = 0 \text{ (conjectural variation terms)}$$

The Cournot market solution is reached by setting marginal revenue for each duopolist equal to zero (*i.e.*, the point of optimal production under the assumption of no costs) and solving the resulting equations.

$$(1) \qquad px_1 = 25x_1 - x_1 \frac{(x_1 + x_2)}{3}$$

$$(2) \qquad \frac{dpx_1}{dx_1} = 25 - \frac{2x_1}{3} - \frac{x_2}{3} - \frac{x_1}{3}\frac{dx_2}{dx_1} = 0$$

$$(3) \qquad x_1 = \frac{75}{2} - \frac{x_2}{2}.$$

Similarly,

$$(4) \qquad x_2 = \frac{75}{2} - \frac{x_1}{2}$$

[18] Strictly speaking, if "(c)" holds, there are no channels of firm-policy information since firm policy is made by the decision maker; but in so far as one deals with approximations to the model, "(e)" becomes relevant.

[19] See *Recherches sur les Principes Mathematiques de la Theorie des Richesses* (Paris, 1838), Ch. 7. English translation: N. Bacon, Trans., *Researches into the Mathematical Principles of Wealth* (New York, 1897).

And thus,

$$x_1 = 25 \qquad (5)$$
$$x_2 = 25$$
$$p = 8.33$$

To explore some of the implications of this paper, assume that in the market specified above, Firm 1 and Firm 2 have reached the equilibrium point specified by the Cournot solution and are both producing 25 units. Next, assume that the market demand increases, such that

$$p = 30 - \frac{x_1 + x_2}{3}$$

Under the assumptions previously outlined, it is predicted that Firm 1 will tend (a) to be slow in changing its perception of the market demand, (b) to underestimate demand when its perception does change, and (c) to give a positive value to the conjectural variation term. Thus, Firm 1 might have expectations with regard to the market demand function and the conjectural variation term as follows:

$$p = 25 - \frac{x_1 + x_2}{3}$$

$$\frac{dx_2}{dx_1} = 1$$

Similarly, it is predicted that Firm 2 will tend (a) to change its perception of market demand quickly, (b) to overestimate demand, (c) to give a value of zero to the conjectural variation term. Thus Firm 2 might have the following estimates of key information:

$$p = 100 - x_1 - x_2$$

$$\frac{dx_1}{dx_2} = 0$$

Under these conditions, the market solution deviates significantly from the standard Cournot solution.

$$x_1 = 10$$
$$x_2 = 45$$
$$p = 11.67$$

The effect is to make Firm 2 dominant in the market.

Note that the solution above will be stable only if the new production level and the resultant profits are acceptable to the dominant control groups of the two firms. If, for example, the control groups of Firm 1 are not satisfied, they may demand a reorganization of the firm. Specifically, they may insist that its organizational structure be more like that of Firm 2. Such a reorganization would have obvious consequences for the estimation of demand, etc., with a resultant impact

upon the market. In point of fact, it is possible to specify a set of values for organizational structure and the aspiration level of control groups such that a market which has, under standard economic analysis, a given equilibrium point has, with the addition of the organizational factors, either a different equilibrium point or no stable equilibrium at all.

IV. *Program for Empirical Analysis*

In this paper a framework has been presented for dealing with certain variables which have not previously been formally introduced into oligopoly theory by economists but which, nevertheless, seem to be significant. That framework, and the hypotheses suggested, have been based explicitly upon a substantial body of empirical research previously reported in the literature of economics and the other social sciences. However, further refinement and testing of the hypotheses advanced here depends upon research specifically directed toward that end. While it is not the intention here to indicate in detail the types of empirical study that are being used to test the theoretical structure proposed above, some indication of the research program may be desirable.

Three stages of research are projected. On the basis of the framework outlined above, a myriad of models could be constructed by imputing values to the variables and by taking various combinations and permutations of these variables. Consequently, it seems clear that the most economical first step to be taken is a study within the theoretical framework defined in this paper of a number of firms in oligopolistic markets, with the goal of determining the patterns most commonly observed in the organizational variables specified above. Secondly, with constraints thus imposed upon the organizational variables, it will be possible to approximate more accurately the quantitative relationships existing. At this point, it is believed that the facilities of the laboratory can be exploited, since it is possible in the laboratory to study the effects of a single variable (or pair of variables, etc.) while holding others constant.[20] Such manipulation is ordinarily impossible in the study of

[20] In general, economists have not utilized laboratory studies to validate propositions concerning firm behavior to the same extent that students of the other social sciences have. On the basis of the experience of social psychologists in the use of the laboratory for the observation of organizational phenomena, it seems possible to utilize such techniques for the study of pricing behavior. For example, Harold Guetzkow, of the Carnegie Institute of Technology, has recently developed a laboratory design for testing certain propositions in organization theory. In his design, individual participants assume roles in sales and production departments in a firm and attempt to maximize firm profits in an experimentally standardized environment. Tests are made of the differences in profitability associated with differing organizational structures. It is anticipated that such a design can be modified, or a new design of this type developed, to provide experimental tests for the hypotheses relating pricing behavior and the organizational characteristics discussed in this paper.

existing organizations, although under some conditions environmental circumstances may, in essence, duplicate an experimental situation by providing examples of all possible combinations of values for the variables under examination. The advantages of the laboratory stem from the opportunity to guarantee such examples. Finally, on the basis of the clarification provided by the laboratory results and the preliminary field study, a set of hypotheses appropriate to actual situations will be made. These hypotheses will be in the form of specific predictions of the dimensions of price behavior listed above and will be tested systematically against actual organizational and market data. In this fashion, the hypotheses generated will be accepted or rejected and a further refinement of oligopoly theory will be feasible.

MORE ON THE MULTIPLIER EFFECTS OF A BALANCED BUDGET[1]

By William J. Baumol and Maurice H. Peston*

It seems to have become widely accepted among economic theorists that an increase in government expenditures on goods and services matched by an equal rise in taxes, will, subject to qualifications to be indicated presently, tend to result in a rise in national income equal to the tax-expenditure change.[2] In this paper we shall maintain that this argument is likely to be misleading in two respects. First, it suggests that there is something unique about the theory of the balanced budget multiplier which differentiates it sharply from other multiplier theory, in particular, because, as we shall see, the public's marginal propensity to save is alleged to be irrelevant for the process.[3] Second, the argument is misleading in that it appears by a feat of magic to be able to determine an empirical magnitude (the value of the multiplier) without the use of any empirical material. We believe that in this respect, though it involves correct deduction from its peculiar premises, the unit multiplier argument is really likely to be an irrelevant tautology because, as we shall argue, in practice there is very little assurance that unity is even a rough approximation to the multiplier associated with any balanced-budget expenditure program which a government may be expected to undertake.

Indeed, we have no reliable evidence on which to preclude even negative balanced budget multipliers or multipliers considerably in excess of unity. To a large extent this is the result of "leakages" in govern-

* The authors are respectively professor of economics and research assistant in economics at Princeton University.

[1] Most of the substance of this paper we owe to Professor Viner and Mr. Turvey. The former spent much time and effort in convincing one of us of the error of his views on this matter and a considerable part of our analysis can be traced to a rather obscure passage in the cited article by Turvey (pp. 284-86 [see end of this paper for all references]) where he had come to the same conclusions. While they both made highly useful suggestions on an earlier draft of this note they can, of course, not be held responsible for what happened to the baby after we adopted it, any more than can Professor Chandler who was our severest and most helpful critic. We must also express our gratitude for very useful comments to those who attended the faculty-graduate meetings of the economics departments of the University of California at Berkeley and Stanford University where this paper was given.

[2] *For an extensive list of references see* Samuelson's article, p. 140, footnote 5.

[3] But see Gurley's paper for a unified treatment which fits the balanced budget case directly into the general analysis.

mental expenditures, some of which have already been noted in the literature implicitly or explicitly. But we believe the full extent of their ability to affect the magnitude of the multiplier has not been recognized.

Our argument will be seen to apply equally well, *mutatis mutandis*, to all multiplier analysis, but it seems to us that the misunderstanding has been greatest in the balanced budget case.

We can perhaps best review the argument in question by quoting the following passage from Wallich (pp. 79-80), one of the original expositors:

> Suppose that national income is at a level of 130 billion dollars, and that this leaves without employment resources capable of producing ten billion dollars worth of goods and services. Now the personal income tax is raised to yield an extra ten billion dollars, and this money is employed, say, to build more roads, provide more free education, etc., previously idle resources thus finding employment. Incremental taxes and expenditures are so adjusted that the consumption and saving habits of taxpayers as a group are the same as those of the newly employed who are the recipients of incremental government expenditures. It is true that the additional tax reduces by ten billion dollars the purchasing power of those who are employed to begin with; this purchasing power, however, is not destroyed, but merely transferred to the hands of the newly employed. Since in their joint effect the additional taxes and expenditures are, by assumption, non-progressive, the consumption demand exercised by the newly employed will be the same as that which would have been exercised by the initially employed, had they not had to pay the tax. Aggregate private demand and private output therefore remain unchanged, but meanwhile there is an increase in government output equal to the ten billion dollars produced by the previously unemployed, which is paid for out of taxes and therefore is not dependent upon the level of aggregate demand. Thus national income has been raised to a total of 140 billion dollars.[4]

There are several well-known provisos attached to the argument:

1. The expenditure in question must involve a governmental purchase of goods and services rather than a transfer payment.[5] For a transfer payment merely redistributes income, and adds no governmental effective demand for output to that of the public.

2. The propensity to consume of the recipients of the expenditures

[4] Note that this argument attributes no peculiar powers to government. If it is valid, the same effect could, for example, be produced by a firm which simultaneously increased its saving and its investment expenditure by the same amount (*cf.* Samuelson, p. 151). It might be thought (as we did) that an equal change in imports and exports will also have a unit multiplier effect. But this is not so because, while a governmental balanced budget purchase will (at least initially) reduce the excess supply of goods available to the private sector, imports will increase supplies by just the amount they are decreased by the change in exports.

[5] See *e.g.*, Wallich, p. 82; Samuelson, pp. 142-43.

must, on balance, be the same as those of the payers of the tax.[6] Otherwise, even a transfer payment can affect national income if it takes money out of the hands of nonspenders and gives it to spenders. And governmental balanced-budget expenditure on goods and services will affect national income by changing private demands as well as by increasing the government's demands, and so increase national income by more or less than the amount the government spends.

3. The government's program must not affect the level of private investment. In particular it must not affect businessmen's views on the profitability of investment.[7] If, for example, they are led to fear increased governmental competition or if the taxes affect their incentives adversely, their reduced investment could offset some or even all of the expansionary effects of a governmental balanced-budget expenditure program. Similarly, businessmen's confidence in the program's ability to increase effective demand might further increase its effectiveness.

4. A closed economy is sometimes assumed. The reasons for this are not explained, though they are perhaps regarded as obvious.[8]

All of these qualifications already suggest that in practice a balanced budget might cause national income to go up by considerably more or less than the amount spent by the government. Later considerations will indicate that income might sometimes even be reduced.[9]

Though the effects of taxes have been mentioned in the literature and have already been referred to, there is somewhat more to be said in this connection. The unit multiplier argument takes the collection of T dollars in taxes to be equivalent to that much of a reduction in the public's income. For only then can it be argued simply that if taxpayers and expenditure recipients have the same marginal propensities to consume,

[6] See, *e.g.*, Haavelmo [1] p. 311, Wallich, p. 80; Samuelson, pp. 140, 141 footnote 6. It is also assumed by several of these writers that household saving is the only leakage in the system. Peston (pp. 129-30) has shown, however, (challenging Turvey on this point) that the balanced budget theorem is consistent with the existence of other leakages, and with indirect taxes in particular.

[7] See, *e.g.*, Wallich, p. 38; Samuelson, pp. 140, 141 footnote 6

[8] See, *e.g.*, Haavelmo [1] p. 314, but see White, p. 357 for an explicit discussion Another qualification which has received considerable attention in the literature involves the possibility of lags Thus if there is a time lag between the receipt of the taxes and their disbursement, only the long-run multiplier will approach unity. See the papers by Haberler, Goodwin, Hagen and Haavelmo [2] Other types of lag can be handled in the same way--for example there may be a lag between the time a businessman receives the money spent by the government on goods out of his inventory (when part of the money just adds to his liquid capital) and the time he hires labor, etc., to replace this inventory at which time that portion of the money first constitutes income.

[9] Most of the points raised in the next five paragraphs are made in considerably greater detail in White's valuable article where they are raised as part of a general discussion of the problems of empirical multiplier computation. But no mention is made of the consequences for the balanced budget multiplier theorem

the government's tax expenditure program will not affect private consumption demands. But taxes are ordinarily not the poll taxes of pure income redistribution theory. Besides their income effect they usually also have some substitution effects and result in changes in plans other than what might be expected to follow from a simple change in income.

Perhaps most obvious is the case of a general sales tax which, in so far as it is a tax on consumption, may encourage saving at the expense of consumption. Thus a given increase in tax receipts, if obtained in this way, may reduce consumption expenditure more than would the same reduction in disposable income. We may suspect, therefore, that the government's expenditure of the same amount will not raise the public's consumption by as much as its taxes have reduced it. In this case, the multiplier will be less than unity.[10]

For the same reasons we may expect that a tax on savings or a (foreseen) capital levy which is matched by an equal governmental expenditure on goods and services may well have a multiplier effect greater than one as people rush out to increase their consumption in an effort to avoid the taxes. Death duties and capital-gains taxes too may conceivably cause less of a contraction in the public's expenditures than does a simple reduction of disposable income by the same amount. A tax on imports (tariff) may actually even increase consumer demand for domestically produced articles, particularly if the elasticity of demand for imports is very high. Even if the money is collected out of ordinary income taxes, the balanced budget multiplier cannot be presumed to be unity, for people's incentives to earn income may be affected.

Having examined the assumptions on the nature of the tax structure inherent in the unit balanced budget multiplier argument we shall now, in a similar way, question its premises on the nature of governmental expenditures. The passage from Wallich quoted above suggests that the sort of governmental expenditure program to which the unit balanced budget multiplier argument is meant to apply is typified by road building, free education and the like. But such programs usually involve, to at least a small extent, the purchase of items other than domestically currently produced goods and services. While they may involve no transfer payments, they will usually include some purchases on capital account rather than on income account, and they will usually have some import content. For example, road or school-building construction often

[10] In Turvey's model such a situation yields a multiplier of zero because he assumes a "money illusion" which leads people to keep their money expenditures unaffected by sales taxes. In other words, consumption is made a function of disposable income, which is defined as receipts from factor sales plus transfers minus income taxes; and indirect taxes are made a function of consumption.

involves the purchase of land which affects the seller by increasing his liquidity rather than his income. This may induce him to spend more, but presumably not as much as the amount by which the taxpayers have reduced their expenditure.[11] The result will be similar if some of the government's purchases involve imported ingredients or items obtained out of unwanted inventory, old buildings, etc.

The existence of these "leakages" in a governmental tax-expenditure program—the nonredistributional effects on private consumption, the purchase of items on capital account and of goods from abroad—is, of course, well known, though no attempt seems to have been made to take account of them in the literature. Possibly some of the writers had them in mind but considered them unimportant, since presumably none of them considered the unit multiplier figure as more than an approximation to the empirical magnitude in view of the recognized qualifications. The magnitude of the leakages may indeed be rather small, and it is very tempting to conclude that if 10 per cent of the government's balanced budget expenditure is "leaked," the multiplier will be reduced from unity to say about 0.9. However, we argue now that fairly small leakages can even produce a negative balanced budget multiplier.[12]

Suppose, for example, that T dollars end up being collected in taxes all of which are spent in various ways, many of which involve some sort of leakage. Let us say, then, that of this amount only E dollars end up being added to expenditure on domestic goods and services coming out of current production.[13] National income will then end up being increased by the E dollars of the increased income-creating expenditure, but it will be reduced by private expenditures foregone as a result of the $E - T$ dollar reduction in private disposable income. Taking c as the marginal propensity to consume, this reduction in private expenditure, as is well known, is represented by

$$c(E - T) + c^2(E - T) + \cdots + c^N(E - T) + \cdots = \frac{E - T}{1 - c} - (E - T)$$

$$= \frac{E - T}{s} - (E - T)$$

where s is the private sector's marginal propensity to "save," that is

[11] Of course, this does involve a change in private investment but not necessarily a change in the inducement to invest.

[12] For a result which is structurally the same as the following see Higgins, pp. 394-95.

[13] Note that T and E represent final taxes and income-creating expenditures Actually, for example, T dollars may be collected as a result of a different amount, T^*, of new taxes being levied. For, by affecting the private sector's expenditures, the tax measure may affect the amount of taxes collected with any given tax structure. Similarly the legislated increase in expenditures may differ in magnitude from the increase actually attained, *e.g.*, because of the effect on employment compensation payments. For an analysis in terms of the taxes and expenditures initially undertaken, see Turvey.

to save, import and purchase items not currently produced or replaced.[14] Thus the total change in income, ΔY, will be given by the sum of this expression and the initial E dollar contribution to national income. This gives

$$\Delta Y = E + \frac{E - T}{s} - (E - T) = \frac{E - T}{s} + T.$$

The multiplier will then be

$$\frac{\Delta Y}{T} = \frac{E - T}{sT} + 1$$

which has a unit value in the special case where $E = T$.

Let k be the proportion of the tax not being added to income-creating expenditures so that $(1 - k)\ T = E$. Then our multiplier becomes

$$\frac{\Delta Y}{T} = \frac{(1 - k)T - T}{sT} + 1 = \frac{1 - k - 1}{s} + 1 = 1 - \frac{k}{s}.$$

Thus the multiplier will be positive, zero, or negative as the marginal propensity to save and import of the private sector is greater than, equal to, or less than k, the government's "marginal propensity to leak."

We can see now how misleading is Haavelmo when he argues that ". . . [Kaldor's] statement would seem to convey the idea that taxes equal to public expenditure can create employment only to the extent that they cut down on people's savings. This is not correct. We shall show below that public expenditures covered by taxes have an employment-generating effect which is *independent* of the numerical value of the propensity to consume."[15]

In line with what might be expected intuitively, our analysis indicates that a balanced-budget expenditure has an expansionary effect only if the government's "marginal propensity to leak" is less than the public's, that the expansionary effect will vary directly with the size of the public's marginal propensity to save, import, etc.,[16] and that the unit

[14] It will be noticed that c is not the straightforward marginal propensity to consume of elementary macro-theory. Rather it is the marginal propensity to consume currently domestically produced goods and services which are renewed. The significance of many of the leakages referred to in the text is that sometimes a consumption change involves a change in investment in the form of imports or inventory variation This, however, is not necessary to ensure a balanced budget multiplier other than unity.

[15] Haavelmo [1] p 312 The italics are Haavelmo's See also the approving reference to this in Samuelson, p 141, who objects to the conclusion only in the unstable case where $s = 0$.

[16] It is perhaps rather paradoxical to conclude that the magnitude of the balanced budget multiplier will be larger the greater is the marginal propensity to "save" of the private sector. The explanation is quite simple. Some of the money the government taxes away will not be returned to the public as income. The damaging effect will then be minimized if the public would have "saved" a large proportion of the income of which it has been deprived.

multiplier analysis is a direct consequence of the assumption that the government's marginal propensity to consume out of current domestic production of goods and services is unity. In this way we have removed the apparent peculiarity from the theoretical structure of the balanced budget multiplier which can now be seen to fit in directly with other multiplier analysis.

Furthermore, the analysis suggests that negative multipliers (or multipliers considerably greater than unity) are by no means out of the question.[17] We do not have adequate empirical information to assert that government's marginal propensities to import are typically smaller than those of the private sectors. Moreover, purchases on capital account may usually constitute a small proportion of public works expenditures but we really know very little about the magnitude of the private sector's marginal propensity to save or purchase on capital account against which this should be balanced. If we follow the usual multiplier analysis in assuming away any effects which occur outside the consumption sector, then business leakages are irrelevant. Of the remaining leakages certainly the average private propensity to save in this country has usually been rather small (about 1/20 to 1/10) and if the corresponding marginal propensity is anywhere in this neighborhood it might not take much in the way of governmental leakages for balanced-budget expenditure programs to exercise a contractionary effect on national income.

If the business sector were included in the discussion, we would add both to the induced expenditures and to the induced leakages. The average propensity to save would then no longer be negligible, but in this situation saving would only be a leakage if it were not undertaken to increase investment, *i.e.*, if it represented hoarding. This suggests that, if the public's marginal propensities to import and buy on capital account were the same as those of the government, the balanced budget multiplier might typically be rather close to zero. For the derivation of the usual proportion of the increased governmental revenue from excise taxation might, by discouraging consumption, tend to offset the small expansionary effect which works through the public's propensity to hoard. Of course, this sort of reasoning is always treacherous, and really insufficient to establish a presumption that the multiplier will in fact be low. Our aim is merely to indicate that on the information now available this possibility (among others) cannot be ruled out, and to suggest that *we really do not know much about its magnitude.*

In fact, there is no reason to believe that the magnitude of the balanced budget multiplier will remain unchanged with changing time and

[17] On this point the exposition in Baumol and Chandler is rather unsatisfactory. See pp. 349-51. But *cf.* p. 371, question 1.

circumstances. The following remark is presented primarily as an illustration of one way in which such variation may come about.

If it is true that the public's marginal propensities to save and import fall in a depression and rise at higher income levels, the expansionary effect of a governmental tax-balanced expenditure will tend to be reduced during periods of low national income and increased in more prosperous times. For, as we have seen, the higher the private sector's marginal propensity to "save," the lower will be the balanced budget multiplier. Thus an increase in balanced-budget expenditures may have untoward effects at all times, aggravating the cycle at both extremes.[18]

This result may perhaps be supported by an observation which involves the asset position of consumers. During a depression it is not unlikely that some people's consumption expenditure will be financed out of borrowing (which frequently takes the form of unavoidable arrears on rent payments, grocery bills, etc.). If it is assumed that these loans do not involve a decrease in consumption on the part of lenders, then, *ceteris paribus*, their repayment—in so far as it involves directly only an asset variation—will constitute a leakage in any expansion program. In other words, consumption out of a given income will be less than normal while consumers restore their net asset positions. It must be noted that often they do not have much choice in this matter. In addition, this consideration seems to lead to the conclusion that the sooner the expansion program gets under way, the larger will be its multiplier effect although other factors may be working in the opposite direction.

Of course, the government is not entirely powerless in these matters. By deliberately altering the composition of its purchases it can manipulate its "marginal propensity to leak." For example, a successful "Buy American" program could raise the balanced budget multiplier.

[18] A. G. Hart has suggested to one of the authors that the effect of investment on the balanced budget multiplier may work in the opposite way over the course of the cycle. The matched taxes and expenditures can reduce the liquid assets of business firms if they are designed to transfer purchasing power from nonconsumers to consumers. Many firms seem to be willing to invest out of borrowing only when it is supplemented by the flow of their own savings. In such a case their marginal propensity to invest may exceed unity. Thus any associated reduction in the earnings of business firms may, through its effect on investment, substantially reduce the magnitude of the balanced budget multiplier in prosperous, or even in moderately depressed times. In deep depression, argues Hart, investment will be at a minimum. Only absolutely unavoidable expenditures of this sort may be undertaken. Since the demand for investment will then be relatively inelastic the balanced budget multiplier will not be much affected by any reduction in disposable corporate income which results from an equal increase in governmental expenditures and taxes.

BOOK REVIEWS

Economic Theory; General Economics

The Goals of Economic Life. Edited by A. DUDLEY WARD. (New York: Harper Bros. 1953. Pp. x, 470. $4.00.)

The Organizational Revolution. By KENNETH E. BOULDING. (New York: Harper Bros. 1953. Pp. xxxiv, 286. $3.50.)

These are the first two volumes in a six-volume study of Christian Ethics and Economic Life sponsored by the Department of the Church and Economic Life of the National Council of the Churches of Christ in the U.S.A. Charles P. Taft, chairman of the Department, explains in the foreword that this group recognized "that we need a more careful and realistic investigation of economic life and its relation to spiritual and moral values. . . . Accordingly, as a beginning of such an investigation, a three year research study was commenced in 1949 under a grant from the Rockefeller Foundation" (pp. viii and ix). *Goals of Economic Life* is a symposium in which economists, political scientists, theologians, and others attempt to assess the ethics of present-day economic goals; *The Organizational Revolution* is one of the more detailed studies in the series. These books cannot be ignored by anyone who is concerned with the ethical aspects of economic life.

The responsibility for passing ethical judgment upon our economic institutions was neglected by Protestantism until recently. Therefore, this semi-official attempt by American Protestantism to evaluate economic activity by Christian ethical standards is a step in the right direction. But the authors of these two volumes, while they sense a conflict between Christian ethics and our economic behavior, shrink from a fundamental examination of the problem. They tend to accept and to rationalize the traditional mores of Protestant Americans rather than to seek out the Christian ethical standards and use them as a basis for evaluation. As I explain below, the dust jacket statement that "the purpose of this important series is to define how ethical standards apply to the realities of earning a living and keeping the national economy stable and progressive," reveals the task actually undertaken by the books.

There are two important ways in which this statement of purpose and these volumes avoid a Christian appraisal of American economic life. First, they substitute "ethical standards" in general (by which is usually meant the standard of justice) for the Christian ethic of universal love. Confusion on this point is not, unfortunately, confined to these volumes; it is rampant in Christian groups today. Secondly, the widely accepted economic goals of American life, stability and progressiveness, in the sense of the achieving of ever higher material standards of living, are assumed, almost without discussion in these volumes, to be either good or essentially beyond the limits of ethical appraisal.

Professor Boulding's chapter in *Goals of Economic Life*, "Economic Progress as a Goal of Economic Life" presents a stimulating and unorthodox discussion of the measurement of economic progress; but it deals only briefly and superficially with what should be its central concern, the Christian evaluation of material progress as a goal. In general the authors do not even seriously question the ethical validity of material progress as a goal. Boulding acknowledges that: "The saints have usually seen clearly how the power to satisfy desire —of a worldly sort—itself increases the desire . . ." (p. 73) and admits that "There is much wisdom in this prophetic criticism of the quest for riches, whether on the part of an individual or a society" (p. 74). But this wisdom can apparently be dismissed in a couple of brief paragraphs.

Walton Hamilton gives similar cursory treatment to the wisdom of the ages. He observes that to the Christian Fathers, at least through the time of Aquinas, man held earthly possessions "in trust from God." On the next page he says, "A dominant moral requirement of our society is free play for the dynamic urge" (pp. 260-61). How this becomes "a moral requirement" for a Christian society is not, however, made clear.

To return to our first point: The distinction between the Christian standard of universal love and the classical standard of justice is ignored throughout most of these two volumes. Only Reinhold Niebuhr in the concluding chapter of *Goals of Economic Life* deals explicitly with the distinction. His treatment while tranchant seems seriously in error to the reviewer.

I agree that "any religious faith which merely discovers the law of love but does not also make men aware of the other law, that of self-love, is a sentimental perversion of Christianity" (p. 439). His error lies in his willingness to accept as Christian, "a practical compromise between the law of love and the law of self-love" (p. 441). In a crucial passage (p. 440) Niebuhr says: "It was an achievement of Catholic moral theory that it recognized the necessity of standards of justice for the institutional life of mankind below the level of love. But it was a weakness in the theory that love became a 'counsel of perfection' and lost its dialectical relation to the law of justice."

Niebuhr, it seems, is ready to accept justice as the "practical" ethical standard if it is recognized as a "tentative and provisional" standard and is kept in a "dialectical relation" to the law of love. He apparently accepts justice as the "practical" Christian ethical standard in the belief that it is unrealistic to appeal to men to live up to the law of universal brotherly love. But just such an appeal to men to live by the law of universal brotherly love is the distinctively Christian ethical standard. Niebuhr's position, it seems to me, renounces the prime ethical contribution of Jesus Christ: That man should love his neighbor—*and his enemy too*; that he should meet injustice by going the second mile, by giving the cloak to the taker of the coat; that he should be perfect even as his Father in Heaven is perfect. This is the essence of Christian ethics. The gospels make it apparent that Jesus Christ did not regard these teachings as too extreme for ordinary men. His commands for action on the basis of love, not justice, and for perfection, not for being a little better, were given to ordinary men—fishermen, tax collectors, etc.

The experience of St. Paul is also instructive on this point. As a Pharisee he

strove valiantly to obey the Jewish law—the commands of justice—and failed. As a Christian he tried to live according to the commands of love, honestly trying to treat all others as brothers, as members of the family, and he found it—contrary to all reason—more possible than trying to live by the law of justice.

The insights of modern psychology in support of the validity of the law of universal brotherly love are developed by Professor Snygg in his chapter on "The Psychological Basis of Human Values." Of all the papers in this book it seems the most pertinent contribution to the search for Christian goals. He presents a theory of human behavior which he calls the individual field approach (pp. 348-55). The individual seeks self-enhancement through role fulfillment. Snygg relates this approach to economic activity and to ethical behavior. Although he does not explicitly refer to religious authority, his statement is obviously couched in the terms of the Christian ethic when he says, "Law and ethics can help prevent injustice that we can recognize, but the best insurance against injustice is complete identification with the potential victim so that injury to the victim is injury to the self. The man who loves his neighbor as himself has not abandoned self-interest. He still seeks for self-maintenance and enhancement, but his self now includes his neighbor" (p. 359). Snygg recognizes the difficulties of achieving identification with an all-inclusive group. He wonders whether "it may follow that a man who loves all of mankind equally will not love any one person much" (p. 361). It should be noted that he reaches no conclusion. The point is crucial and needs more study. The experience of St. Francis and John Woolman should be reassuring on this point. Another answer may lie in his earlier suggestion that, "The ideal sought is a state in which the individual feels so much in harmony with the universe, so much a part of it, that he does not have to defend himself against any other part. It is significant that this state is said to have been achieved, at least in moments of ecstasy, by some of the saints. It probably involves the perception of the universe as one completely pervaded with infinite love and compassion for all living things. From this point of view the higher religions represent man's greatest insight in their recognition of the ultimate goal of human endeavor and their audacious attempt to move directly toward it" (pp. 352-53).

I have quoted these portions of Snygg's paper at length not only because of their intrinsic importance and relevance to Niebuhr's chapter, but because they shed light on important points in Boulding's book. Boulding rejects love as the ethical basis for large-scale organization on the basis of "laws of organizations themselves." "The family type of intimate relationship which is the highest expression of the spirit of love in human life," he writes, "can be achieved only *in an organization* of family size—i.e., a mere handful of people." "A society . . . which tries to apply a familistic ethic to a brontosaurian organization, will end," he asserts, "in a terroristic rigidity" (p. 178).

Boulding does not undertake to support by detailed discussion or citations the conclusions quoted above. In a volume on organization in a series on Christian ethics such cavalier dismissal of the basic Christian commandment as a principle of organization is unfortunate. It is particularly unfortunate

when the conclusion is contrary to competent professional opinion expressed in an earlier volume of the series, for while Snygg is agnostic on the possible success of *universal* love as an organizational principle, he evidently believes that love is a workable basis for groups well beyond family size. Snygg tries to come to grips with the problem of whether love, the distinctively Christian ethical standard, is an adequate motivational basis for organized society; Boulding simply rejects it, essentially without discussion.

Niebuhr, although he accepts Snygg's suggestion that "human existence, when profoundly analyzed, yields the law of love as the final law of human freedom," believes that "politics (and for that matter economics too) must assume the selfishness of men" (p. 439). He states as a "basic assurance," "that men must be engaged primarily through their self-interest to participate in . . . economic life . . ." (p. 434). This is something quite different from the mere recognition of the selfishness of man as a (regrettable) fact. It is the acceptance of self-interest and the scrapping of the Christian law of love as an organizational principle of economic life. Niebuhr is in distinguished company in his rejection of "the benevolence of the butcher, the brewer, or the baker," as a basis for economic motivation. The imprimatur of the professor of moral philosophy in the University of Glasgow that there is nothing ethically objectionable in self-interest as a principle for economic motivation is widely accepted among English-speaking Protestants.

There is incidental questioning of this idea in the present volume; for instance, Neibuhr calls attention to the dubious nature of Adam Smith's "assurance of the beneficent effect of the [unseen] hand." Similarly, Hamilton notes that, "Adam Smith, unlike many of those who now quote him, was too moral a man to venerate self-interest in the raw. . . . He would . . . if necessary have society interfere with its controls to make certain that the pursuit of gain was made to serve a public purpose" (p. 261). And J. M. Clark recognizes as a problem the fact that the market mechanism is not neutral as a device for choosing wants which are to be satisfied. Professor Bennett in his chapter "A Theological Conception of Goals for Economic Life" goes even further. He draws attention to "the moral dangers in a society that puts its chief emphasis upon the motive of self-interest." The capitalistic theorist "assumes too readily the innocence of self-interest because in a competitive society those who are seeking their own profit are supposed to be serving the common good. We have learned from bitter experience that the cultural support for unlimited acquisitiveness trains men in tendencies to which they are already inclined and causes them to develop institutions for the exploitation of the community in their own interests" (p. 412). "Persons are corrupted by the moral climate created by great emphasis on personal financial gain, by false standards of success, by almost unconsciously dishonest advertising and salesmanship, by the commercial stimulation of materialism and vulgarity in popular tastes. This subtle type of corruption instead of providing clear moral issues, the facing of which produces character, undermines character before people are aware of what is happening" (p. 418).

Unfortunately, however, none of the authors deals at all fully with the

ethical problems posed for the Christian by the self-interest motivation. There is a general willingness throughout these volumes to accept this motivation with little question. There is only vague recognition of the fact that, if self-interest is served by society and accepted as a proper motivation, then the self-love aspect of human nature will be nourished while further growth of the other more divine aspect of human nature, love of others, will not be promoted. Thus in our society the selfish aspects of human nature are given greater relative dominance. Such dominance of self-interestedness may well threaten our whole social and economic structure for, as J. M. Clark notes, it is essential that "the sense of right [should become] an increasingly active feature of economic life, and social responsibility in the use of group power has become an absolute necessity, if the industrial system is to go on working on a basis containing enough freedom to be fairly characterized as voluntary" (p. 25). It is not enough, as Niebuhr seems to suggest, that the Christian law of love have a "dialectical relation" to the law of justice. The goal of Christianity is that the law of love become the basis of action and thus transcend and hence replace the law of justice, not that it merely progressively elevate the law of justice by its dialectic contrast. To say that this goal is unattainable is to reject the very specific commandments of Jesus Christ.

Within the limits of a review it is impossible to deal fully with the contributions of each of the fifteen authors of *Goals of Economic Life* separately. Attention should be called to a few outstanding points. Clark presents a series of admirable vignettes on the development of some ethical aspects of economic doctrine; and Danhof, Hamilton, and Boulding comment suggestively on the history of European and American economic and social ideas. Heimann's paper on "Comparative Economic Systems," while difficult to follow, comes close to the central issues in its appraisals. We must await with high expectations a more complete treatment in his promised book. Linton provides a challenge with his anthropological basis for an evaluation of our economic institutions. Unfortunately he does not relate his anthropological insights to Christian values.

Because most of the authors of *Goals of Economic Life* accept the law of justice as the Christian ethical standard, these essays (with the exception of Snygg's) fail to study seriously the really basic question which the Christian should ask about economic life: Can the concept of love of others as the basis for action serve as the organizing principle of an economic system, and if so, how?[1] Neither do these essays examine the question which is at least implicit in Niebuhr's analysis: How should our "tentative," "provisional" and "relative" standards of justice be revised and elevated through a "dialectical relation" (Niebuhr's term, not Marx's) with the law of love?

The ethical question which occupies these authors for the most part is the important but much less challenging one: How do American economic practices fall short of the ethical standard of justice which Americans generally accept?

[1] Boulding in *The Organizational Revolution*, as noted above, declares without serious study that universal love is unworkable as the basis for *social* organization.

As an answer to this question the symposium is a success. However, in a more basic sense it is a disappointment because the participants in this ambitious study to do not come to grips with the fundamental problem: a really Christian ethical appraisal of economic goals. These papers show no evidence of the "more careful and realistic investigation of economic life" which Mr. Taft outlined as the aim of the study. They present, rather, the ethical ideas which are held generally by American Protestants.

In spite of this shortcoming the book should be read by those who are concerned with the application of ethics to economic life. The book has a high level of economic literacy, which is often lacking in such discussions. As collateral reading for advanced undergraduates it should prove stimulating and instructive.

Boulding's analysis in *The Organizational Revolution* is more sociological and political than it is economic. For such an anlysis an economist may not be the appropriate critic of another economist's efforts. His principal thesis is "that the organizational revolution of our time has been in the main the result of certain technical changes in the ability to organize: changes both on the physical side in the improvement of transportation and communication, and on the structural side in the forms and skills of organization itself" (p. 49). The development of loyalty patterns which have made possible loyalties to organizations other than the family, the church and the state, has been of at least as great importance. When they could command loyalty, large, complex, far-flung organizations persisted for centuries in premodern times, even if they did not function efficiently. On the other hand, the corporation functions poorly in many areas today not because of lack of technology but because of lack of loyalty. Loyalty to economic organizations and what Boulding calls "the 'minor virtues'—honesty, truthfulness, punctuality, faithfulness in the fulfillment of promises, sobriety, attention to business" (p. 140) are the keys to the remarkable development of organization in the modern world as much as technological changes.

Boulding's analysis of organizations has the shortcomings pointed out earlier: it accepts progressiveness or as he terms it, "the spirit of enterprise" as the important thing (p. 158) and it fails to see the dangers of the Smithian self-interest solution. He reflects the curious ambivalence in Protestantism. Love is described as the major Christian virtue (p. 140) but self-interest must be relied upon for political and economic organization. This uncertain attitude toward the Christian ethic of love is epitomized when he rejects love as the organizational principle for any organization larger than the family on page 178 and then, on page 198 appeals for world organization on the basis of love.

Boulding's case studies of the ethics of the labor movement, the farm and business organizations and the national state as organization are instructive although a bit unfair to labor and too kind to farmers and business.

CALEB A. SMITH

Brown University

A Study in the Theory of Economic Evolution. By TRYGVE HAAVELMO. (Amsterdam: North-Holland Publishing Company. 1954. Pp. 114. $2.00.)

Haavelmo puts the question in an interesting and novel way: how are we to explain the fact of gross economic dissimilarities? Why is one country rich and another poor? Why is one region economically and technologically advanced and its neighbor primitive? This is one of those tricky problems where it is only too easy to find answers, too many answers, and the fine art of the theorist is to pick out the illuminating and fruitful ones. At the very beginning Haavelmo rules out the easy verdict that "people are just different" —which explains everything and therefore explains nothing. He argues that the basic idea underlying and justifying international development programs is that the human material is essentially homogeneous. The theory that goes along with this practice should proceed from the same assumption. This is not at all to deny that the process of economic development itself leaves deep and irreversible marks on the capacities and motivations of people. In his formal mathematical models Haavelmo tries to introduce this powerful effect by including a variable which stands for the cumulated level of education and know-how. He makes it depend somehow on income or capital per head and in turn it works on the technological level, the birth rate, and perhaps the propensity to save of the population. If he does not completely succeed in making the model ring true, who is to cast the first stone?

A case could be made that Haavelmo underrates the importance of such factors as climate and resource endowment. After all, there are no "developed" tropical countries and hardly any "developed" nonindustrial countries. This is unlikely to be sheer accident. But even so, one can find enough cases which are not explainable on these grounds so that much force remains in Haavelmo's argument. We may leave aside also the influence of social and cultural variation (Calvinism, for example). Formal economics must draw the line somewhere.

This leaves three by no means mutually exclusive sources of dissimilarity to investigate: differences in structural parameters, differences in initial conditions, and the cumulative effect of random disturbances. Most of the book is given over to discussion of these, partly in terms of a series of mathematical models, and partly in general terms, but always abstractly, even philosophically. It is easy to see that in growing systems even minor differences in structural parameters can build up eventually into great divergences. If one identical twin starts with an inheritance of ten dollars and the other with nine and if their bank pays 3% compound interest, then the first will be much richer than the second by the time they are as old as a country can get to be. Alternatively if their inheritances are equal but the first twin's bank pays 3.01% their fortunes will again diverge. In the first case, the twins' bank accounts will remain forever in the same ratio in which they started, although as both grow rich the difference between them increases. One could argue that in this case the ultimate difference is really "no greater" than the initial difference, properly measured. After all in any dynamic system it is hard to say what

one means by "minor" differences in parameters, other than those which give rise to "minor" differences in development. In the second case, not even the ratio of the twins' fortunes remains constant; by this criterion there is no such think as a minor difference in rates of growth. Perhaps one should not consider such long periods—but this question cannot be decided on a high level of abstraction. In any case Haavelmo has much of interest to say on such questions.

The role of initial conditions is even more interesting, and Haavelmo seems to lay greater weight on them. His nonlinear models show what linear models never can: that initial conditions can be of fundamental importance. With the same structural constants, some starting-points can lead to growth, others to stagnation or decline. There are "humps" to be climbed. Even here there are subtleties and paradoxes. It is not always clear what are initial conditions and what are structural parameters: the distinction is economic not mathematical. Moreover, to ascribe differences in development to differences in initial conditions seems like begging the question. Initial conditions are only the results of previous development. But again to draw the line somewhere may not be as arbitrary as it sounds, especially when we take account of the irreversible aspects of economic and social history.

The chapter on the effects of random shocks on growing systems is on the technical side, but its conclusion is that such unpredictable and uncontrollable events can easily have the effect of creating, preserving, and even magnifying the long-run results. If our twin brothers, now with the same inheritance and the same bank, engage in tossing a fair coin it is quite likely that one will wind up supporting the other.

The book ends with an interesting discussion of "economic history as an irreversible process of trial and error." There should be some room for the notion of social choice in models of economic growth. I have no idea what the prospects are for progress in this direction. The long run is deceptively hard to analyze, if only because analytical errors, along with everything else, get magnified.

ROBERT SOLOW

Massachusetts Institute of Technology

Monopoly and Competition and their Regulation. Edited by E. H. CHAMBERLIN. (New York: St. Martin's Press. London: Macmillan. 1954. Pp. xvi, 5549. $7.50.)

This book incorporates the product of the Round Table meeting of the International Economic Association which was held in Talloires, Haute Savoie, France in September 1951. In addition to 24 papers it includes a substantial summary record of the debate prepared by Elizabeth Henderson. The papers may be said to fall into three fairly distinct categories: (1) those descriptive of the market structure, the character of public policy, and the cultural values and attitudes prevalent in various countries with respect to competition and monopoly; (2) those dealing primarily with theoretical issues; and (3) those dealing with public policy objectives and techniques.

The country papers deal with Canada (V. W. Bladen), France (R. Goetz-

Girey), Italy (F. Vito), Union of South Africa (W. F. J. Steenkamp), United Kingdom (G. C. Allen), United States of America (R. B. Heflebower), Western Germany (F. Boehm), and Scandinavia (H. Brems). These papers are on the whole disappointing. To begin with, the information available on market structures and patterns of behavior in most, if not all, countries is woefully inadequate. Information is adequate only in connection with legislation affecting competition and monopoly. As a consequence some of the papers tend to be no more than a summary and rather spiritless description of the law of the land as it affects competition and monopoly. Second, there is evidence that (with some exceptions) the problem to which the authors address themselves is not of vital concern to them. This should not be especially surprising. The issues under discussion have aroused much more intense interest and public debate in the United States than anywhere else in the world. The general outline of the issues which the authors were asked to examine reflects an American's conception of the issues—a conception which contrasts rather sharply with its European counterpart. One has the feeling that, if the participants had been given a much freer hand in formulating the problems, the country papers might have been stimulating and provocative. Vito's remark that in Italy "competition as such is not highly rated in our value system—it receives appreciation within the limits it contributes towards a superior aim of community life" brings home in a rather striking fashion the issue of cultural relevance of the problems under discussion. Heflebower's optimistic statement concerning the extent and the desirability of competition in the United States is matched by the scepticism of the European participants both as to the extent and as to the desirability and feasibility of competition in their countries. Characteristic in this respect is E. A. G. Robinson's statement in the course of the debate that "listening to successive American speakers, he had felt as if (he were) listening to a 'harmony glee club.' " Finally, with regard to the country papers, W. F. J. Steenkamp's discussion of the relation between the growth of an underdeveloped economy and monopoly contains a number of highly promising insights.

Among the theoretical papers there are some truly outstanding contributions. J. S. Bain's discussion of "Conditions of Entry and the Emergence of Monopoly," S. Lombardini's "Monopoly and Rigidities in the Economic System," and P. Hennipman's "Monopoly: Impediment or Stimulus to Economic Progress" represent top-drawer performances and should be put high on the reading list of specialists in the field. The other theoretically inclined papers contain much that is interesting, but do not extend our horizon to any significant extent. These papers include Joan Robinson's "The Impossibility of Competition," E. H. Chamberlin's "Measuring the Degree of Monopoly and Competition," I. Svennilson's "Monopoly, Efficiency, and the Structure of Industry," Jane Auber-Krier's "Monopolistic and Imperfect Competion in Retail Trade," K. Rothschild's "The Wastes of Competition," and F. Machlup's "Monopoly and the Problem of Economic Stability."

It is impossible to discuss the content of individual papers. An attempt might be made, however, to state the general character of the approach and the sense of problem that dominates most if not all the theoretical papers. To

begin with, there seems to be general agreement that traditional theory concerning market structure and associated behavior and performance is dead but not quite buried. It is clear that the doctrine of "workable competition" has made substantial inroads in the thinking of the theorists. It is also clear, however, that no systematic body of thought has been formulated which can be substituted for traditional structure-behavior-performance theory. Some of the papers strive to formulate such a theory in terms of behavior or conduct (emphasizing such things as *active* competition, or competitive pressure, or potential competition, etc.) whereas others attempt to associate structure with performance in a more direct fashion. There is general dissatisfaction with static analysis—but no attempt is being made to replace it completely with either a dynamic or an evolutionary, growth-oriented model. One is left with the feeling that traditional neoclassical doctrine is most inadequate in explaining or predicting behavior or performance from structure—but that the task of putting something in its place has barely begun. Similar remarks can be made in connection with the standards, welfare criteria or value systems in respect to which the performance emerging from structures is to be evaluated. All agree that perfect competition as a standard is dead. The substitute in most cases, however, seems to take the form of *ad hoc*, casuistic theorizing.

The last group of papers deals with problems of public policy rather than theory. F. A. McGregor's paper on "Canadian Techniques" should provide much food for thought to American students of antitrust law and its enforcement in the United States. The papers by W. J. Jöhr on the "Regulation of Competition" and J. M. Clark on "Competition and the Objectives of Government Policy" are highly readable. It is of some interest perhaps that the public policy papers tend to treat competition as a concept of conduct rather than as a concept of structure or performance. The "workable competition" which emerges from these papers tends to be formulated in terms of behavior patterns rather than in terms of market results. C. D Edward's paper on the "Issues in the Monopoly Problem" may be classed in the public policy category though there is much in it that deals with theory. It contains a list of highly penetrating questions. It is an excellent statement of the state of ignorance of the profession. Finally, one should mention W. A. Lewis' "Recent British Experience in Nationalization" and J M. Jeanneney's "Nationalization in France." Both papers serve to emphasize the fact that nationalization *per se* solves no problems—that the question of objectives and criteria of public policy may be raised as acutely in the "regulation" of nationalized as it is raised in the regulation of private businesses

It may be evident by now that the reaction of this reviewer to the volume as a whole is rather mixed. Quite a few of the papers are masterpieces. Some are rather mediocre and run of the mill. Even the best, however, do no more than raise the problems with which this generation of economists must deal, if it is to make any contribution to the issues of theory and policy which it has inherited from the past.

A. G. Papandreou

University of Minnesota

Uncertainty and Business Decisions—A Symposium. Edited by C. F. CARTER, G. P. MEREDITH and G. L. S. SHACKLE. (Liverpool: The University Press. 1954. Pp. viii, 101. 10*s*, 6*d*.)

This volume contains seven papers delivered at a meeting devoted to discussion of the problem of decision-making under uncertainty, with special reference to the ideas put forward in G. L. S. Shackle's *Expectation in Economics.* A brief summary by Shackle of his own theory helps to make the book self-contained, and there are several additional, minor contributions.

Shackle's views cannot be adequately summarized here, but the most crucial contentions are the following. (1) The decision-maker will associate a degree of "potential surprise" (y) with the value (x) of each possible outcome of a course of action; "surprise" is a psychological magnitude, not connected with "frequency-ratio probability." (2) Courses of action will be evaluated by the decision-maker *exclusively* in terms of two outcomes—those which attain the highest favorable and unfavorable values on a psychological "stimulation-function" $\varphi(x,y)$ (stimulation varies inversely with y and directly with the absolute value of x). Shackle's theory is descriptive, arguing that men do behave in the way indicated, not that they necessarily should. It is a psychological theory of decision: it argues, for example, that men ignore mathematical expectation—which, as an "unappealing, unexciting abstraction," is supposed to lack the power to stimulate the mind.

D. J. O'Connor accepts Shackle's theory as an explanation of subjective expectation, but argues (following Russell) that some kind of theory of objective *credibility* is still needed. O'Connor, unlike Shackle, accepts the frequency interpretation of probability as a guide to credibility for some situations, maintaining only that a rather different guide is needed for situations which are unique or unrepeatable. Such a guide may be needed for situations which are "unique" in the sense that probabilities are completely unknown. Shackle also claims, however, that even where probabilities are known they are *irrelevant,* provided that the decision is unique or unrepeatable (for example, if it involves a large fraction of one's wealth or life itself). This view is surely wrong. If life or death depends on calling correctly the fall of a not necessarily fair coin, no reasonable person would find recorded frequencies of heads and tails for that coin irrelevant for his decision.

C. F. Carter points out that if the φ-function is to have a definite maximum, both x and y must be defined as cardinal magnitudes. Carter criticizes Shackle's theory for its arbitrary concentration on just two outcomes and also for its assumption that all outcomes with equal surprise have the same "degree of belief," using the latter term to indicate subjective probability valuation.[1]

[1] Carter is correct in sensing a difficulty with Shackle's theory here, though his discussion of it is confusing because he fails to mention that he defines "degree of belief" differently from Shackle. The latter's "degree of belief" is a function of two surprises—that associated with a hypothesis and another with its contradiction, while Carter's is a simple subjective probability ordering. That there is a difficulty with Shackle's definition is indicated by the following example. By Shackle's Postulate 9, at least one possible hand of 13 cards at bridge must carry zero surprise. The contradiction of the hypothesis that I will receive this hand (*i.e.*, the hypothesis that I will receive any of all the other possible hands) must also be

To avoid these difficulties Carter presents a revised theory of expectations. Possible outcomes are divided into groups according to degree of belief, and courses of action are examined by comparing their outcomes for each possible state of the world, each such state (*e.g.*, war next year) being associated with a particular degree of belief. Carter, though he perhaps does not realize it, is on familiar territory here: unlike Shackle, he really views the problem of decision-making under uncertainty along traditional lines, the only substantial departure being his insistence on grouping the outcomes into a small number of ordinally defined equal-belief groups (this is due to a supposed inability of the human mind to contemplate a continuous variable). Carter's prescription for action differs, however, from the traditional one (maximizing expected utility, with subjective or objective probabilities as weights) because of the ordinal nature of his degrees of belief. In general, his prescription will not lead to a solution; that is to say, except in special cases where something like dominance exists, there remains an irreducible doubt. This is possibly a fruitful idea (it is related to some of Shackle's work)—interesting consequences can perhaps be drawn from a theory of indecision, though Carter does not pursue the question further.

Lack of space precludes detailed discussion of several other contributions. W. B. Gallie argues that analysis of "what is contingent or irreducibly uncertain" in human affairs has been slighted as a result of failure to realize that scientific laws do not and can never totally depict reality. While this view of scientific laws seems reasonable, there is a long history (starting with Bayes and D. Bernoulli) of thoughtful analysis of the problem of decision-making under uncertainty which Gallie ignores. B. R. Williams stresses the importance of uncertainty in various parts of economic theory, especially the theory of profit.

Some special mention must be made of the paper by I. J. Good, which is a fascinating hodgepodge of methodological ideas, definitions, remarks and suggestions defying brief summary. Good maintains a subjective theory of probability, outlined in his valuable book *Probability and the Weighing of Evidence*. The reader should be warned, however, that Weaver's "surprise index" discussed by Good is no close relative of Shackle's, being an inverse of elements in a probability distribution rather than a psychological magnitude.

Because of the extraordinary dependence of Shackle's theory upon his special (and therefore refutable) hypotheses about the psychology of the decision-making process, interest naturally attaches to the contributions of G. P. Meredith, a psychologist, and A. D. Roy, whose topic was the possibility of testing alternative theories of uncertainty. Unfortunately, Meredith in discussing a wide variety of topics neglects Shackle's crucial psychological contention: to wit, that one single point on the favorable side of the φ-surface has the power to eclipse all other favorable outcomes and concentrate all

---

assigned zero surprise (footnote on p. 113 of *Expectation in Economics*, 2nd ed., and Postulate 6). But then my degrees of belief (Shackle's definition) in the two hypotheses are equal (by Postulate 1). This is completely unreasonable.

attention on itself; and similarly on the unfavorable side. Roy does not propose any specific tests, indicating that the alternative theories are as yet so incompletely developed that case studies are likely to yield more information than experiments.[2] Both postulates and consequences of Shackle's theory, however, do seem sufficiently clear to warrant an attempt to square theory with observation. Shackle himself has pointed out a discrepancy here—his theory appears to have the consequence that a speculator will in general hold all his resources in only two assets. The absence of comparisons of fact and theory or of modifications of theory in the light of such comparisons is the chief cause of a certain disappointment the reviewer felt in the volume.

JACK HIRSHLEIFER

The RAND *Corporation*
Santa Monica, Calif.

[2] A survey of various experiments bearing on the economic theory of choice may be found, however, in W Edwards, "The Theory of Decision Making," *Psych Bull.*, July 1954, LI, 380-417

Wirtschaftssysteme und Gesellschaftssysteme. By EDUARD HEIMANN. Veroeffentlichungen der Akademie fuer Gemeinwirtschaft Hamburg. (Tuebingen: J. C. B. Mohr (Paul Siebeck). 1954. Pp. xii, 250. DM 16.50; cloth, DM 19.80.)

Through these pages vibrates the passion of a writer who wants his message to be heard. The volume offers economic analyses, sociological essays, theological observations. But all that is only a means of conveying the message: Only a rejuvenation of Christian faith can make possible a creative solution of the mortal threat to western civilization.

This statement of what seems to be the final aim of this book may appear to disqualify it for a review in a professional journal of economics. Nevertheless, I appreciate it that the editor of the *American Economic Review* wants this book brought to the attention of the profession. This is justified on two grounds.

1. Heimann has brought together in this book the German translation of a number of studies published in English during the last twenty years.[1] These contain valuable but not easily accessible contributions to the literature on major socio-economic topics. The analyses of planning in totalitarian and liberal societies; the role of labor unions, trends in agriculture, class struggle, imperialism and colonialism, these and others will be of interest even to those who dismiss Heimann's main message as "nonscientific."

2. Furthermore, in our age of specialization in economics, it is necessary to remind the student of economics of the essential unity of the social sciences. In working on specialized economic topics he should remember the noneconomic assumptions which usually are taken for granted. Heimann demon-

[1] About one-third of the book has been written especially for this publication. Also, previously published parts are so edited and supplemented that the book is now somewhere between a systematic treatment and a collection of essays. There is a great number of references to other works by the same author, some published, others in manuscript form.

strates this unity once in his book by the following example: ". . . the smooth operation of the [market] economy requires a certain degree of reliability and compatibility of the people, and this minimum is assured through the spiritual-moral-religious characteristics of the society at the present time" (224). He then raises the question as to whether under present trends the continuation of these prerequisites of the modern economic organization is assured. Another example is related to the quasireligious element in Marxism which is important for an understanding of Soviet Communism; or the question as to the spiritual aspirations of the former colonial countries which is decisive for an understanding of the economics and politics of the underdeveloped countries. A work which deals with these relationships between spiritual and ideological developments and the developments of economic institutions and processes should be of interest to the economic profession.

One of the main concerns of the author is to elaborate on the contrast between and the similarity of capitalism and communism. These he regards as the two pure systems of what he calls "economic rationalism." He believes that it is common to both systems that economic values (such as maximization of income or consumption) are established as the purposes of the economic process, separated from their cultural and social context. These systems alone lend themselves therefore to the development of economics as an autonomous, separate science. Both systems are based, however, on unrealistic and evil philosophical assumptions—individualism in the one case, collectivism in the other. Both do violence to the dignity and freedom of the human being in the social community (p. 240) which Heimann regards as two interrelated supplementary concepts. That these systems can work to some extent in reality is due to the fact that "the secularized society is viable as long as it still has the unofficial religious inheritance at its disposal" (p. 226).

Heimann regards capitalism (that is, *laissez-faire* capitalism) and communism as pure types and not as anything existing in reality. He sketches the economic system as it is evolving in Western countries under the title of "Liberal Democracy." This appears as a kind of capitalism mitigated by social reforms. He also contrasts both capitalism and communism with socialism. He defines socialism not by any specific institutional arrangements (such as the conventional nationalization of industries) but by reference to a variety of institutions which may develop under a "common faith" (p. 41). His examples are cooperatives, public corporations (like the Tennessee Valley Authority or the British Broadcasting Corporation), private foundations, and private enterprises in fields in which competition can be effective. Socialism consists of nontotalitarian planning and noncapitalistic markets.

A considerable weakness of the book lies in the fact that Heimann has failed to clarify the relationship between the historically evolving systems of "liberal democracy" and his concept of socialism. At times one has the impression that Heimann would like to say that through the force of social, political and economic exigencies we are somehow drifting in the right direction of a truly viable and quite effective economic system. And then it seems he cannot quite accept this theory because that new system should be created in connection with a religious rejuvenation of which only the first pioneers have appeared

(p. 240) and their impact on the remaking of western civilization can at best be in its beginnings.

In spite of a number of questions and reservations concerning the analyses and interpretations of the book I wish that it could be made available to English-reading economists. I say this because the author is struggling with truly important problems which are not adequately discussed in our professional literature. Here they are treated by a competent scholar in a spirit of great sincerity, although I feel that he has not succeeded in fully integrating his religious concern with his socio-economic analyses.

GERHARD COLM

Washington, D.C.

Sulla teoria matematica della economia politica. By G. B. ANTONELLI. Edited by G. Demaria. (Milan: R. Malfasi. 1952. Pp. 126. L. 1,000.)

G. B. Antonelli (1858-1944) was an engineer of considerable professional standing who, like so many others trained to that vocation in the nineteenth century, felt impelled to augment the literature of the burgeoning science of economics also. In a spectrum of engineer-economists he probably deserves a place nearer, say, to Launhardt than to Sorel or Pareto, for his interest in economics was scarcely perdurable; he made only two major incursions into the field—fifty years apart. Nevertheless, one of these—the essay which has afforded the title and the reason for the small volume noted here—may well be of interest to economists with a theoretical bent, and Professor Giovanni Demaria deserves thanks for having rediscovered and reprinted it.

The book itself consists of three related items, all of which appeared in the *Giornale degli economisti* in 1951. In addition to the title-piece (first published in 1886 as a monograph) there is a prefatory historical note by Demaria and an exegesis of Antonelli's mathematics by Giovanni Ricci, professor of analysis at Milan, which among other things contains (pp. 96-98) a most persuasive discourse on the role of mathematics in economic analysis.

Theorists and chroniclers of theory may find the book interesting in several respects. One of these is that Antonelli's essay, which was originally intended to be the introductory chapter of a full-scale treatise on economics, was the first of a considerable number of rather aridly mathematical disquisitions on "pure economics," a genre which at the hands of Barone, Amoroso, and a host of others was to become in time a sort of specialty of the country. (At the time Antonelli's essay first appeared, Pareto was still a political feudist rather than an economic theorist.) Furthermore, aside from denoting, so to speak, a point of inflection in the trend of Italian economic literature, the essay possesses substantive interest. For one thing, the skill with which Antonelli deployed his files of equations and phalanxes of determinants in traversing the treacherous terrain of utility and price theory is remarkable since, economically speaking, he was *autodidattico.* Again: Antonelli was probably the first (anticipating by twenty years Volterra's criticism of Pareto's *Manuel*) to raise the thorny question of the integrability—*i.e.*, validity—of utility functions where more than two goods are involved (pp. 29-32).

As is quite proper in view of its historical nature, several typographical

errors have been perpetuated in this reprinting, for example on pages 19, 20, and 25. But this has not made Antonelli's essay easier to read, and some at least will find more nourishment in the explanatory articles which sandwich it in than they will in the Antonellian meat.

A. STUART HALL

University of Illinois

The Determination of Production: an Introduction to the Study of Economizing Activity. By BURGESS CAMERON. (New York: Cambridge University Press. 1954. Pp. xv, 100. $3.75.)

Boiling down the greater portion of basic economic theory to an even hundred pages is a considerable feat in itself. To do so without substantial loss, and even with a greater flavor of realism than is generally found, as it seems to me Cameron has done, is remarkable indeed.

Cameron's emphasis is on the general equilibrium of the system. He develops the theory by presenting a series of nine models, each involving some further generalization of the preceding one. Beginning with the case of consumption in fixed proportions and production with fixed technical coefficients, the model is modified in successive chapters to include consumer choice, factor substitution, investment, money, etc. and discussion is given to such matters as location, the state, monopoly, size of firm and so on. Most of the models are illustrated by numerical examples.

The result is a book which differs from the usual text in a number of ways. Most noticeable, and in light of the subtitle, perhaps most surprising, is the fact that the theory is exclusively positive: there is a complete absence of welfare theory as such. Secondly, the emphasis on general equilibrium and its presentation by successive models means that such topics as consumer theory, the theory of the firm, etc., appear as successive qualifications to the theory; they are not first treated individually and then put together as a system. In other words, the theory of the firm is an elaboration of the general theory of production, the latter is not built up from the former. However, since the successive modifications of the model require separate treatment of these topics, the pedagogical difference is less than might appear at first sight. The emphasis on general equilibrium likewise leads to an integrated treatment of the problems of allocation of production on the one hand and determination of the aggregate level on the other. There is thus no sharply marked break in the analysis as is so often the case.

Finally the hypothetical examples which are worked out are cast in a framework which, it seems to me, tends to offer the student a better background for understanding both the nature of and the limitations to modern empirical analysis. As an outstanding example, discussion of the linear model in Chapter I is accompanied by a fold-in input-output table for a hypothetical twenty-industry economy.

This is not to say that Cameron's ideas are all entirely beyond dispute. For example, I am disposed to quarrel with his practice of including a "normal rate of profit" in the early models where there is no investment, and of stating

it, even in later chapters, as a per cent of output. Nor does his reference to holding money as a "hedge" strike me as a happy use of the term. But it would be a drab book indeed which failed to offer some occasion for difference with the author.

Brevity of presentation is not achieved without cost. Although one does not have the feeling that the style is unduly terse, the book may not prove to be an easy one for the average student to master without considerable guidance. Nevertheless, the volume will provide an excellent text in a senior or first graduate course in economic theory for the instructor who prefers a brief, competent starting place for his own elaboration.

DANIEL B. SUITS

University of Michigan

Economics. By RICHARD C. BERNHARD. (Boston: D. C. Heath. 1954. Pp. xiv, 801. $6.00.)

For the aim of this principles textbook this reviewer has nothing but praise. The author has paid more than lip service to the ideal of presenting economics to the beginning student as a part of the larger field of the social sciences and, indeed, of the whole body of man's knowledge. It is refreshing to find an economist who, on a single page, can make meaningful references to the works of Whitehead in philosophy, Wigmore in law, Born, Oppenheimer, and Planck in physics, Pareto and J. N. Keynes in economics (p. 715). The author's short note (pp. 236-37) on ". . . current literature in which unemployment is a background or setting. . . ." fills a need which many principles teachers must have felt when trying to bring home the broader effects of depression to present-day students who have no personal recollection of the nineteen-thirties. Unemployment and national income statistics and price indices are hardly adequate to give the picture of that era for today's college sophomore. The perceptive novelist has a very real contribution to make.

When we turn to the technical analysis there are some disappointments. Micro-economics receives a full treatment. Demand analysis is, however, based on diminishing marginal utility rather than indifference curves—a deliberate choice made for pedagogical reasons. Part of the analysis, particularly that of elasticity of demand, is carried beyond the level of difficulty with which the average sophomore can successfully grapple.

Macro-theory, however, does not appear to receive the space or rigorous analysis which it deserves in view of its position in modern economic thought and its importance for national policy. I hasten to add that the author does not slight it because he believes, as some do, that if we ignore Keynesian economics it will go away. (His apt characterization of Henry Hazlitt's ideas on depressions is that they are "antediluvian.") His statement that, "The problems of economic fluctuations are now stated in terms that are more satisfactory [than saving and investment] and the explanation is supplemented by the concept of saving and investment" (p. 281) needs elaboration and substantiation. Many economists would not agree that Lutz' article in the *Quarterly Journal of Economics* (Aug. 1938) is "definitive," in this regard.

The chapter on "Economic Myths and Superstitions on the Subject of Depressions" is a worth-while and stimulating innovation.

Emphasis upon and space allocation for institutional material in principles textbooks are to a considerable degree matters of taste. This book gives a very full treatment of business, labor, and international institutions. The omission of agriculture is unfortunate, however, for this field is not only a controversial one with regard to policy, but also offers the student an opportunity to use some of the analytical tools he has learned earlier in the course. Considerably more attention is paid to the relation of economics to law and to statistics than in most beginning texts. There is also fuller treatment of a war economy—the stepchild of economics—than is generally found.

This text is elaborately footnoted, which is ordinarily pedantic pretense in a principles text since few students will read footnotes and the instructor presumably is familiar with the literature. But in this work many of the footnotes serve a very useful purpose in directing the ambitious student and his instructor to materials outside the field of professional economics which can be studied with pleasure and profit by both.

Economics can be recommended without reservations for the beginning course. It is, perhaps, best suited for those principles courses which are oriented towards students not majoring in economics or business administration.

Economic History; National Economies; Economic Development

Britain and Industrial Europe, 1750-1870: Studies in British Influence on the Industrial Revolution in Western Europe. By W. O. HENDERSON. (Liverpool: The University Press. 1954. Pp. vii, 255. 25*s*.)

The appearance of a new work which stresses the international aspects of the origins of industrialization in Western Europe is a welcome occurrence, not alone for economic historians, but also for scholars and officials whose concern is with that most recently sprouted of the branches of economic science and policy—the economics of underdeveloped areas. Dr. Henderson, senior lecturer in international economic history at the University of Manchester, is well qualified to deal with this topic in view of his previous work on *The Lancashire Cotton Famine, 1860-5* (1934) and *The Zollverein* (1939), as well as his many articles dealing with the economic expansion of Germany. Although he makes no pretense of writing a complete history of British influence on continental industrial development, he has dug deeply and skillfully into a wide variety of sources, both manuscript and published, to bring to light much new information and to correct some old misinformation. His use of contemporary literature and reports of government commissions is particularly noteworthy.

In an introductory chapter the author states that Englishmen influenced the industrial development of Western Europe in three ways: (1) emigration of

skilled workmen who installed new machinery and instructed native workers in its use; (2) the activities of British entrepreneurs and managers abroad; and (3) the export of British capital. In addition, he points out the significance of continental industrialists who studied or traveled in Britain. In the chapters which follow he is primarily concerned with the first two instrumentalities; his book is, therefore, a useful complement to Leland Jenks' *Migration of British Capital to 1875* (1927), which thus far has stood virtually alone in its treatment of this topic.

The main body of the work consists of eight monographic studies (some previously published) on aspects of the development of France, Belgium, Germany, and "Central Europe" (which in this case consists of the Habsburg dominions, Holland, and Switzerland). Three deal with specific episodes, the others with more general topics such as the textile or metallurgical industries. The studies are grouped by country, France rating three totaling 91 pages, Belgium one of 37 pages, Germany three in 55 pages, and "Central Europe" only 17 pages.

British influence was most pronounced in France and Belgium, considerable in Germany and Switzerland, of much less significance in Holland and the Austrian Empire. Although the author does not explicitly draw the conclusion, it is clear that direct British influence was at its peak between 1830 and 1860. Prior to that time communications were inadequate and social conditions unfavorable for the rapid diffusion of techniques, even after they had once been transplanted. Subsequently, there was a less pressing demand as the once-backward countries, notably Belgium and France, themselves began to export the instruments and techniques of modern industrial enterprise.

Incidental reference is made to the activities of British workers and entrepreneurs in Spain, the Scandinavian countries, and Russia. There is, however, no mention in the text of either Italy or Portugal, although British influence in the former in the middle decades of the nineteenth century was enormous, and the latter was virtually an economic satellite of Britain. Although Portugal, certainly, was not a part of "industrial" Europe, the omission of Italy is a serious gap. In another connection, had the author paid more attention to the activities of financial institutions and the export of capital he would have found still further evidence of British influence: for example, in the early Swiss railways before they were taken over by French and native Swiss entrepreneurs. On the whole, however, he is correct in placing the emphasis on men, machines, and techniques; the export of capital was of importance mainly as a vehicle for the former. In the instances when capital went abroad unaccompanied, as in government loans, it turned out more often than not to have been of little effectiveness in promoting industrialization.

Most readers will applaud the brevity of the volume, as well as its precise scholarship, but there are a few trivial defects of composition which mar its readability. Much material which belongs in the text is to be found in the voluminous footnotes, and in places the text itself tends to resemble a catalog, as when the author reels off the names of English artisans in a particular locality. Also, the nature of the individual studies results in some repetition.

On the other hand, the elaborate footnotes, the well-chosen titles in the 17-page select bibliography, and the very thorough index will all be of considerable value to scholars working in this and related areas. And for a wider audience, the nature and consequences of the diffusion of techniques of economic development which Henderson has illuminated in this instance will invite comparison with similar phenomena of both past and present.

University of Wisconsin

South African Food and Agriculture in World War II. By J. M. TINLEY. (Stanford: Stanford University Press. 1954. Pp. xii, 138. $5.00.)

This is one of the group of studies sponsored by the Food Research Institute on food and agriculture in World War II. It reviews briefly the prewar position of South African agriculture, describes the evolution of the food and agriculture regulatory agencies during the war, and tells what was done to handle the surpluses of some export products, resulting from the loss of markets in enemy countries or from the lack of shipping, and to meet the shortages of other products due to increased consumption, unfavorable weather conditions or absence of the usual imports. The book goes on to discuss the wartime difficulties encountered, and the measures taken to meet them, in fertilizers and other farming requisites, the wartime employment and food consumption trends, price control and price developments, and the postwar food problems. The final chapter provides a good summary of the book.

One item of particular interest is that South Africa never introduced a formal system of food rationing even though there were periodic shortages of certain foods, especially immediately after the war. The determining factor in this policy was the government's belief that the administration of food rationing in the South African multiracial and culturally heterogeneous economy would be most difficult. The author flatly disagrees with the policy that was followed, stating that difficulties would have been no greater in South Africa than in many other countries. In this regard, my sympathies are with the government.

Strangely, although Professor Tinley is the author of a book on the native labor problem in South Africa, the introductory background section of the book omits any mention of one of the important characteristics of South African agriculture: the dependence on African natives for the bulk of the labor on the European farms. Unless this particular organization of production is appreciated, the low productivity of South African agriculture cannot be understood.

Within the framework that the author accepted for himself he did an excellent job in providing a concise clear description and analysis of what was done in South African food and agriculture during the war. But those readers who are interested in the major problems of South African agriculture, or in the economy of South Africa and the position of the food and agricultural sector within the economy will feel dissatisfied.

The book omits any analysis of the lasting impact of the war on South

African agriculture. For example, what did the war do to the peculiar economic structure of agricultural production? There is no mention made of the contribution of the war towards the elimination of the "poor whites" from agriculture, nor, on the other side, of its contribution towards the spread of the Karoo—the South African semidesert.

A White Paper on agricultural policy issued at the end of the war stated, "Today the farming industry and the country generally are suffering from the results of systems of land use that have been carried on with apparent success as far as production is concerned, over lengthy periods of time, but which are now showing clear signs of breakdown all over the country." "Breakdown" is undoubtedly too harsh a characterization of South African agriculture at the end of the war, but it is fairly clear that South African agriculture responded poorly to the challenge of the war. There is no doubt that Tinley's book would have been more illuminating if it had included an analysis of this problem.

A. M. KAMARCK

Chevy Chase, Maryland

Management of the Industrial Firm in the USSR: A Study in Soviet Economic Planning. By DAVID GRANICK. (New York: Columbia University Press. 1954. Pp. xiii, 346. $5.00.)

This is the fourth in a series of books on the Soviet Union to be published by the Russian Institute of Columbia University. It is the first major work on Soviet industrial management to be published in the West and is based on a study of heavy industry for the period 1934-1941; it extends our knowledge considerably beyond the point to which it was carried in 1944 by Bienstock, Schwartz, and Yugow (*Management in Russian Industry and Agriculture*). It treats many features of the Soviet firm not covered in J. Berliner's recent article (*Quarterly Journal of Economics*, August 1952) nor by A. Vucinich (*Soviet Economic Institutions*, Stanford, 1952), and also corroborates Berliner in those important areas (*e.g.*, the relative unimportance of enterprise profits to managerial motivation) where the studies overlap. Corroboration in this instance serves an important function since Berliner, relying primarily on interviews with displaced persons who held managerial positions under the Soviets, had turned up a considerable amount of information concerning the operation of Soviet enterprises which was at odds with the official picture painted by Soviet economists in their textbook literature and in the more general economic journals. This picture, incidentally, has been accepted by most western economists (see, for example, the writings of H. E. Ronimois). Granick, exploiting relatively untapped sources of data, primarily the Soviet industrial journals and newspapers, but also the financial, political, and legal journals, substantiates Berliner.

The first three chapters of *Management of the Industrial Firm in the USSR* provide background and are "intended to describe the organizational milieu in which management has functioned and the personal traits of the managers which have conditioned their reactions to the Soviet industrial environment."

Chapters 4 and 5 deal with the formation and limitations of the national plans and the role of plant management in their formulation. Chapters 6 through 8 are concerned with the interrelationship between centralized direction of individual plants (and the network of controls employed to this end) and the degree of autonomy of plant management. Chapters 9 and 10 deal with the various (often conflicting) methods by which the success with which a plant has been operated is measured in the Soviet Union. In Chapter 11 some additional material on the penalties and incentives of plant executives is presented. Chapters 12 and 13 "deal with the role of the Communist Party and of mass worker participation in the administration of industrial firms." In the final chapter "an analysis of Soviet firms is made by comparing Soviet industrial organization with Max Weber's model of bureaucratic structure, and some conclusions are offered as to the success of the system in carrying out the ends of Soviet top leadership."

The picture of the Soviet "firm" which emerges from Granick's pen is not a simple one by any means. Indeed it is so complex, and its component forces so difficult to assess, that Granick has made no attempt to develop a theory of the Soviet firm, a shortcoming of his book from the point of view of the economist. But the picture is clearly drawn and is the most realistic available at this date. We see the Soviet enterprise as the basic element in the Soviet industrial-administrative hierarchy. Although enterprise management has the power to make a number of independent decisions, there is no way of predicting which among several possible courses of action will be followed, although some probabilities are implied. Difficulties in predicting enterprise behavior are caused by the fact that Soviet management is faced with a mass of conflicting goals, controls, authorities, penalties and incentives: national goals and priorities conflict with enterprise targets; enterprise targets, of which there are many, are inconsistent with one another so that fulfillment of one involves nonfulfillment of others; the chief bookkeeper is interested in one set of targets, the plant director in another, and the Communist party representative in still another; fulfillment of enterprise goals, which have the force of law, may only be possible by law infringement in some other area; management may be punished for infringing laws to fulfill goals, for not fulfilling goals in fear of infringing other laws, and rewarded for fulfilling goals by infringing other laws; and so forth. In his final chapter Granick fairly satisfactorily explains on rational grounds why such a hodgepodge exists and particularly why the Soviets apply not one but several and conflicting criteria of success to plant management. He might have included in his discussion nonrational factors such as the arbitrary nature of much of the Soviet price system and the problems which arose from the use of 1926-27 prices in industrial planning. He correctly, in my opinion, cautions the reader (pp. 282-83) not to jump to conclusions regarding the relative efficiencies of the Soviet and capitalist economies on the basis of his discussion, and indicates briefly some of the weaknesses from a national welfare point of view of the "rate of return" as the single capitalist criterion of success.

Although Granick carefully refrains from empirical generalizations based

on insufficient data, a temptation in case studies of this sort, I would question his suggestion (pp. 73-74) that imperfections in Soviet planning have resulted in such large amounts of idle capacity as to explain the Soviet policy of encouraging overfulfillment of plans. In fact, Granick himself contradicts this position later in the book (pp. 130-31) in discussing the general Soviet policy of "overambitious" plans.

This is an interesting and scholarly study worth the attention of all persons interested in the Soviet economy, theory of the firm, economic planning, and in the administrative problems of industrial management.

University of Washington

Economic Survey of Europe in 1953. By the Research and Planning Division, United Nations Economic Commission for Europe. (New York: Columbia University Press. 1954. Pp. xii, 314. $2.50.)

In this latest of a series of annual reports on the European economy, the research staff of the Economic Commission for Europe turns its attention to problems of economic development in Southern Europe, an area defined as including Portugal, Spain, Southern Italy, Yugoslavia, Greece, and Turkey. It will come as no surprise to economists who are familiar with previous reports in this series to learn that this is a highly rewarding survey, distinguished both for the richness of its factual material and the acuteness of the analysis.

This survey is a valuable corrective to the easy tendency to lump these countries in with the countries of Western and Northern Europe and to attribute to them all, at least inferentially, broadly similar economic characteristics and problems. In fact, the economies of the Southern European countries reveal easily as many similarities to the Asiatic stereotype of the underdeveloped country as they do to the advanced economies of Western and Northern Europe. Populations are predominantly agricultural; rural underemployment is widespread; illiteracy is common and infant mortality high; cropping practices are inefficient and crop yields low; rural inertia and traditionalism stand in the way of change; mineral exploration and research are retarded; and manufacturing activity is at a low level with its development hampered by the poverty of consumers, the scarcity of skilled labor, the inadequacy of community services, and the low level of savings.

For each of the five countries and Southern Italy, the report offers a critical survey of economic conditions, trends, and policies. The essay on Yugoslavia is of interest not only as a survey of that country's economic outlook, but even more as an account of the emergence in Yugoslavia of a hybrid form of economic organization which would seem to be unique in the modern world. After the break with the Cominform in 1948, the Yugoslav government stopped trying to model its economic system in the image of the Soviet Union, and began its quest for "a specifically Yugoslav form of socialism." What has gradually emerged might be described as bearing some resemblance to guild socialism, though the analogy is imperfect in important respects. There has apparently been no retreat from the principle of public ownership of non-

agricultural productive facilities, but the whole system of detailed centralized planning of economic activity, as *symbolized by rigid production plans* establishing output goals for each industry, has given way by stages to a kind of quasicompetitive socialism, in which an increasing number of resource-allocation decisions are being made via the market mechanism.

The control of industrial enterprises has been formally vested in the workers; that this control is more than nominal may be inferred from the fact that workers, in considering whether to employ the profits of the enterprise for new investment, for community facilities, or for dividends payable to themselves, often chose dividends. The foreign trade monopoly has been abandoned, and enterprises are free to buy and sell abroad on their own initiative, though within the framework of a complex system of export bounties and import levies. Enterprises are also free to make their own decisions with respect to composition and level of output and selling prices. They may in their own discretion invest or disinvest in durable producers' goods or inventories, and they may finance expansion either by reinvesting profits or borrowing from banks.

A steeply progressive tax on the profits of enterprises was to be dropped in 1954 in favor of a flat-rate profits tax of 50 per cent. Dividend payments were to be brought under control, with the share of profits available for distribution to workers falling sharply as profit increases. The central government had decided to abandon its practice of decreeing minimum capacity utilization ratios for enterprises, and "reliance is to be placed instead on a fiscal stimulus to the maximum utilization of capacity in the form of a new tax on fixed capital"—a decision which suggests that the Yugoslav planners may have allowed their admiration for the price system to run ahead of their mastery of price theory.

Though the Yugoslav government has yielded many of its economic prerogatives to the market, it has by no means abdicated its economic role. Investment programming in the area of "social capital"—power plants and steel mills as well as roads and public buildings—remains a direct responsibility of the government. A turnover tax, levied at different rates on different industries, modifies the verdict of the market on interindustry resource allocation. Though sowing patterns in agriculture are no longer prescribed, and though compulsory deliveries were abandoned in 1952, the state is still the sole buyer of some crops and the biggest buyer of others.

The ECE staff wisely refrains from attempting even a tentative appraisal of the results of the new economic policy in Yugoslavia; for not only is the experiment too young to allow of such an appraisal, but its effects would be extremely difficult to isolate in a troubled economic atmosphere dominated by the forced reorientation of foreign trade patterns after 1948, the internal imbalance caused by the impetuous and grandiose planning decisions of the early years, the droughts of 1950 and 1952, and the dedication of 20 per cent of gross national product to defense. While eschewing an appraisal of results, however, the ECE staff, never celebrated for harboring a blind faith in the workings of the free market, cannot resist the temptation to observe that

"current discussions in Yugoslavia . . . emphasize to an almost exaggerated extent the virtues of market mechanisms as regulators of the allocation of resources." What is exaggerated to ECE might not so appear, however, to other observers; clearly the bizarre turn of economic policy in Yugoslavia calls for a more comprehensive and detailed study than ECE is able to provide in this brief but excellent review.

In addition to the country surveys, the report deals on an area-wide basis with achievements and potentialities in agriculture, mining, and manufacturing, and with the internal and external aspects of the key problems of economic development in Southern Europe. The ECE group emphasizes, as potentially remediable causes of agricultural inefficiency in Southern Europe, the traditional but wasteful practice in grain cultivation of fallowing every second year, the antiquated methods employed on latifundia in Portugal, Spain, and Southern Italy, the deforestation and overgrazing of mountain areas, and "the farming of dispersed plots by peasants living in huge townships far away from the land they cultivate." Wheat yields in the area could, according to ECE, be raised by 50 per cent by abandoning the practice of fallowing and substituting an intensive rotation of wheat with fodder plants and special grasses. It is held also that the agricultural potential of certain regions cannot be realized without "breaking up latifundia" and instituting settlement schemes for farmers and farm laborers now living in the vast agricultural villages.

Apart from the special survey of Southern Europe, the report includes the customary review of economic conditions in Western Europe. Despite the preponderance of favorable developments in 1953, including the recovery from the 1952 recession, the improvement in the balance of payments with the dollar area, and the relaxation of strains on the European Payments Union, ECE continues to find symptoms of latent afflictions which belie the apparent good health of the patient. The congenital pessimism of ECE notwithstanding, Western Europe is fortunate to have so skilled a diagnostician; for if Western Europe should stage a full and lasting recovery, it will matter little that ECE is the last to herald it.

Finally, the report contains a brief review of developments in Eastern Europe and the Soviet Union. Probably the most notable change in Soviet economic policy in 1953 was the drive to increase agricultural output by reducing reliance on compulsion and providing stronger producer incentives. These measures included the elimination of a large part of the agricultural bureaucracy, increased farm prices, reduction of compulsory delivery quotas, and more favorable tax treatment of the private allotments of collective farmers. The reforms in agriculture are probably of greater significance than the much-discussed upward revisions of output targets for consumer goods; these prove to be concentrated in the area of metal manufactures, and are of such a magnitude that their realization will apparently not require a diversion of resources presently devoted to capital formation or defense.

KERMIT GORDON

Williams College

Economic Survey of Asia and the Far East, 1953. Prepared by the Research and Planning Divisions, Economic Commission for Asia and The Far East, Department of Economic Affairs, United Nations, Bangkok, 1954. (New York: Columbia Univ. Press. 1954. Pp. xiv, 161. $1.50.)

Recent political developments in Asia have so far overshadowed economic trends that the difficult problems of economic adjustment facing most countries of the region have been all but obscured.

Perhaps nowhere else in the world at present is the preoccupation of governments with economic development more pronounced than in South and Southeast Asia. Yet in many countries of the region the immediate problem is that the prospective level of export earnings and of government revenue is hardly sufficient to provide the increasing amount of resources which governments wish to devote to economic development. As a result there has arisen a sharp conflict between the requirements of rapid growth and of monetary stability.

The Korean War boom had enabled most governments to expand substantially the volume of their expenditure, largely for development purposes. With the collapse of the boom and the subsequent decline in export values and government revenues, unwillingness or inability to curtail expenditures to the same extent as revenue fell, has in many cases led to substantial budgetary deficits and economic instability. Many countries of the region face actual or potential balance-of-payment difficulties. The principal cause lies in the decline in export earnings and delays of adjustment in private consumption to lower levels of income, but budgetary deficits are also partly responsible. The foreign exchange earnings and resources of many countries in the area are approximately back at the level they had held before the Korean War started, the gains of the boom having been used up in the subsequent decline.

Some countries have boldly faced up to the problem; for instance, the Philippines has chosen in favor of orthodox monetary and fiscal policies, while Pakistan by contrast is financing economic development through a deliberate policy of repressed inflation. Intermediate solutions have been adopted elsewhere but in many cases current policies are no more than temporary palliatives. Deficit budgets, offset in their inflationary effects by reduction in private investment or by absorption of foreign exchange reserves, have helped in maintaining expenditure, but any large resort to them leads to a chain of unfortunate consequences, not the least of which is higher export prices, a further drop in exports, greater balance-of-payments difficulties, further depletion of foreign exchange resources, etc.

Such is the dilemma of many Asian governments and such in essence is the kernel of the situation as portrayed by the latest *Economic Survey of Asia and The Far East.* The survey concludes that on the basis of present available resources, and prospects for foreign aid or foreign investment it would be unrealistic to hope for any rapid economic progress since the level of genuine savings for investment is still quite low throughout the region.

In its resolution on the "Economic Situation in Asia," the ninth session of the Economic Commission for Asia and The Far East requested its executive secretary to follow closely the studies arising out of General Assembly resolu-

tions on "Financing of economic development of under-developed countries" and to incorporate in future issues of the annual economic survey the results of inquiries relating to these problems. Accordingly an attempt has been made to focus attention on the development theme in Part I of the *Survey* which consists of four chapters covering regionally, the food position, the export decline, public finance and the process of adjustment, and problems and policies of development. For the first time, Part II—by far the larger portion of the *Survey*—gives an analysis of recent economic developments by countries, for each of the individual countries of the region.

This new arrangement of the *Survey* is a much happier one than the unfortunate attempt in earlier years to devote one chapter to each functional topic. The old arrangement often resulted in forced and unnatural comparisons and contrasts from country to country. The new procedure of highlighting the most significant trends and developments with a penetrating and perceptive regional analysis and then presenting rounded and comprehensive individual countries studies, seems to this reviewer a vast improvement over the old practice. This annual survey is a far more useful and readable document than its predecessors.

JEROME B. COHEN

College of The City of New York

The Future of Underdeveloped Countries. By EUGENE STALEY. (New York: Council On Foreign Relations and Harper and Bros. 1954. Pp. xi, 394. $5.00).

In writing this book Dr. Staley received advice, criticism, and suggestions from a Council on Foreign Relations study group on "The Political Implications of Economic Development." It is to be regretted that this was not chosen as the title of the book—rather than as its subtitle—for it accurately indicates the author's major interest.

Economists who have made an effort to keep abreast of the literature on the various economic aspects of the problems of growth in the underdeveloped areas will find little that is new here in the narrow field of economic analysis. But most of those who have thought on these problems will agree with Staley that economic development is also a massive problem in social and political readjustment and that this country's concern over it is in large part political. This book, therefore, can be mildly recommended to economists, for they will find parts of it imaginative, discerning, and perceptive, as to the internal and international political and social consequences *and* requisites of a concerted effort to "modernize" the economies of those many areas characterized by chronic mass poverty and obsolete methods of production. The breadth of Staley's concern can be indicated by noting that for him "successful development" includes not merely higher levels of real income, widely shared, but also progress toward democratic self-government and social relations, less vulnerability to totalitarianism, the growth of attitudes making for a more peaceful world, expanding international trade and investment, and a strengthening of the defense capacities of free peoples against aggression.

Staley first appraises, and finds compelling, the motivations for economic development from the point of view of the to-be-developed country, the United States, and the world community. He then examines the nature of the Communist appeal, tactics, and practices in the underdeveloped areas and finds them evil and potent. Having thus set the problem, he goes on during the last half of the book to explore what he considers to be the key problems—emphasizing the social and political aspects—which must be solved if "successful development" is to be had. Here he considers capital formation only briefly and then only as a social process. Much more attention is given to such issues as agrarian reform, population growth, "social technology," external aid, and—in a nontechnical manner—the question of "rounded" economic development.

Staley makes clear at the outset his conviction that the extreme contrasts which exist today between the modernized West and the poorer areas of the world as to economic welfare, health, education, and political freedom poses a decisive test for Western civilization and that either the benefits enjoyed by those presently favored will be generalized or they will be lost to all as more and more people embrace Communism. As this suggests, he writes as a man with an extremely urgent message and the book is shot through with value judgments and such words as "good," "bad," and "should." The matters discussed are so complex that often there is not space for a thorough statement of the supporting evidence and analysis and many of the judgments and generalizations must be accepted on trust. Let it be said that the author's is a persuasive pen.

Although he specifically disclaims any such purpose, Staley does set out many of the elements of an "action" program. The final chapter is entitled "Guidelines for United States Policy" and this reviewer often had the feeling he was reading carefully prepared statements for presentation before, say, an important Congressional committee.

This is no uncritical marshalling of only those arguments supporting the case for bigger and better Point Four programs. Staley does not attempt to minimize the difficulties and uncertainties facing attempts by the West to meet the "revolution of rising expectations" of much of the rest of the world. He does great service by repeating, in various ways, that economic betterment "does not necessarily make nice people" and by emphasizing that the conditions under which increased production will lead to the goals of internal democracy and attitudes that make for peace among nations are complex and delicate, change over time, differ as between areas, and can not be accurately forecast. Many readers will wish that his analysis on these important issues had been somewhat more systematic.

Staley distinguishes himself, among those who write that hastening the economic development of the poorer areas is one of the most important tasks facing us today, by recognizing that in some of the underdeveloped areas the danger is great that population increases may match or outpace production growth, resulting in more rather than fewer people living at the misery margin and leading to disastrous political consequences. He does not despair, however,

and while he concludes that the outlook is highly uncertain, he finds some grounds (not very persuasive to this reviewer) for hoping that birthrates may fall much faster than they have in the past. This is a sobering chapter indeed.

Many parts of this book will doubtless find their way into the official records of the United Nations and the United States Congress by way of statements of those favoring greater efforts by the richer countries of the world to help the poorer nations improve their material well-being. A great disservice will be done Staley if such use of his book fails to make clear his convictions that the process of economic growth must be accompanied by great changes in political and social as well as economic structures, that such changes must inevitably be difficult and painful to many and may be in frightening directions, that disappointments are inevitable, and that while the help given by outsiders may well be the difference between success and failure, most of the burden must be borne by local people.

GARDNER PATTERSON

Princeton University

Western Enterprise in Far Eastern Economic Development—China and Japan. By G. C. ALLEN and A. G. DONNITHORNE. (New York: Macmillan. London: George Allen & Unwin Ltd. 1954. Pp. 292. $4.50.)

The authors have set themselves to describe in some detail the history of western enterprise in China and Japan during the last century. Partly, it is a story of the fortunes and misfortunes resulting from government policies and social upheaval in both countries; partly it tells about the impact of western trade, managerial ability and capital investment on societies in transition.

The book is strictly historical, yet it seems strangely contemporaneous. The necessity of foreign contact, in a mixture of fear and expectation on both sides, is very familiar in our days. Had the authors laid more emphasis on technical assistance and foreign advisers, the picture would have been complete—a century of success and failure in stimulating economic development.

The countries started their development around the middle of the last century seemingly under similar cultural, social and economic conditions; yet the development has been completely different. It is the divergence, not the similarity which came strikingly to light in this study. The evaluation of these differences, and the reasons why they occurred, form the most important part of the study. It contains a lesson, a warning against premature generalization.

If there are two patterns, China and Japan, why would there not be five or six patterns of economic development under the impact of western enterprise? We are promised that Malaya and Indonesia are the subject of a parallel study and should look out for at least one more pattern there.

Yet is it tempting to highlight the differences between Japan and China. Largely, these prove to be cultural and organizational. China was complacent and self-sufficient, Japan eager to absorb western dynamics. Only a society

on the move can absorb the impact of a more rapidly moving force without a clash, even though with friction. The Chinese government became more and more disorganized and weak; Japan more determined and strong, perhaps largely because its education had, in the half century before, been much more forward-looking, less classical than the Chinese. Japan bought foreign services; China had to admit foreign bodies but had no control. Significantly, Japanese industry started with a great deal of government direction and participation. Well-designed, this prevented much dissipation of scarce resources. Most likely also, an archipelago like Japan could, in the nineteenth century, be developed with infinitely less social overhead capital than continental China.

What strikes also, is the eagerness, the variety and perseverance of western private trade and industrial enterprise in the second half of the nineteenth century. At least partly, this was based upon a firm belief in western technical and military superiority. Partly, also, it was possible because the unit of enterprise was still much smaller, and foreign settlements were much more manageable. But there must also have been the courage to take risks, a desire to broaden the horizon and capture foreign markets, which are often missing nowadays. As a result, two underdeveloped countries invoked or at least accepted more foreign technicians, management and capital, over a longer period of time than generally is envisaged under present schemes. Most of it was private enterprise, but governments played an important role.

With all its qualities, the reader misses, in the light of after-World War II attempts to accelerate economic development, a picture of the organizational and economic interrelationships between foreign shipping, trade, financing, insurance, industry, public utilities and their influence, as a package, on domestic economy; stimulating some lines of production, hampering some others, giving jobs to some, making others jobless. There is a detailed description of each part of western activity but hardly a synthesis. The inclination to give qualitative rather than quantitive information gave rise to an enumeration of details which are hard to tie together. Perhaps there are not enough statistical data to show, *e.g.*, what percentage of foreign trade or of commercial banking was in foreign hands, and how this percentage changed over time. However, the study makes abundantly clear that the economic and social history of so-called underdeveloped countries over the last century or centuries, written with a view to modern problems of acculturation, is extremely valuable.

EGBERT DEVRIES

Washington, D.C.

Mobilization of Domestic Capital: Report and Documents of the Second Working Party of Experts. United Nations. Economic Commission for Asia and the Far East. (New York: Columbia Univ. Press. 1953. Pp. 334. $2.50.)

In September 1952 a working party of experts met at Bangkok, Thailand to discuss methods of stimulating the flow of domestic capital for development of Asian economies. Sponsored by the Economic Commission for Asia and the

Far East, the meeting was attended by government representatives from 16 countries, including several delegations from highly developed countries. Discussion was limited to three major areas; this volume is a summary of 34 papers read on these three subjects.

Mobilization of Domestic Capital. In most of the Asian countries discussed, moderate progress has been made the past few years in increasing institutional savings. Unfortunately, data are not available on private noninstitutional saving nor on reinvestment of earnings in unincorporated businesses, which are certainly major sources of saving in Asia. Several novel methods of stimulating savings have been tried in Japan and Korea. Uninscribed time deposits with banks enable savers to remain anonymous thus stimulating savings needed for nation building, using escape from the "net worth" tax as an incentive! In Korea time deposits can be made without benefit of interest, but a lucky few, on the basis of a lottery, are paid handsomely.

In most of these countries government saving is a significant part of total saving. Such saving is also convenient in that it can be easily directed toward nation building projects. Though this saving on government account is an important part of *known* saving, it is a less important portion of *total* saving since a large part of private saving is an unknown quantity in Asia.

Industrial and Agricultural Finance and Development Corporations. The finance corporation is primarily concerned with long-term capital loans, while the development corporation furnishes equity capital and assumes responsibilities of fostering and managing new enterprises. Of 25 country-wide institutions discussed in Asian countries, only 5 are of the development type. These institutions are designed to supplement the private capital market, but in some countries this market is so disorganized that the government corporation finds itself doing a large part of the total financing, particularly in the agricultural field. Success of present finance and development corporations has been substantial but not spectacular. Though capital is scarce, some areas seem to be absorbing capital as rapidly as they well can under existing conditions. Several finance institutions of the area report safe investment opportunities limited by the shortage of enterpreneurial judgment and management skill.

The Relation Between Foreign Capital and the Mobilization of Domestic Capital. Three of these papers are theoretical, and one by the ECAFE Secretariat is noteworthy in that it endeavors to set up a simple model by which underdeveloped countries can estimate foreign capital requirements for given investment programs. It is pointed out that most development plans in Asia have estimated foreign capital requirements ignoring induced imports which will result from increased income, and thus underestimated foreign capital needs and misjudged inflationary pressures. The ECAFE Secretariat has done well in making clear to responsible fiscal officials of the various countries the necessity of a theoretical framework in estimating foreign capital requirements for development programs.

Unfortunately, one error runs throughout the discussion (see mathematical appendix, pp. 285-90): *any* income increase is interpreted as inflation, thus

ignoring the effect of any possible increase in productive capacity, with the result that increased income can only mean higher prices. The model chosen incorporates no capital function, so that the beneficial effect of the development program is precluded from becoming apparent in the model. This is a serious error, and a surprising one to find in a conference devoted to capital-development programs. Implicitly, full employment is assumed throughout, which is a dubious assumption in these areas of recognized underemployment.

General comment can hardly do justice to such a collection of papers. It brings together much information found elsewhere only with great difficulty. The United Nations is performing a signal service in publishing reports of such working parties thus making them available to scholars and public officials. I venture, however, that the most important discussions of such conferences never get into the report, and the reader thus feels unsatisfied. Summary reports of the discussion following each paper would breathe life and vitality into what occasionally borders on the dull.

Swarthmore College

Measurement of Productivity in Indian Industry. By R. BALAKRISHNA. (Madras: University of Madras. 1953. Pp. vii. 288. Rs. 15.)

In this study the author attempts to measure over-all productivity in Indian industry compared with the prewar situation, and to establish interregional and interindustrial comparisons of productivity. The basis on which productivity is measured is chiefly the man-hour requirement per unit of output. The approach is different from typical industry case studies in which productivity is assessed by a thorough analysis of many factors involved. The task of this author was certainly made difficult by lack of data.

The first finding of the book is that there was a decline of more than 10 per cent in labor productivity in India in 1948 as compared with 1938. Twelve industries were examined which represented about 77.56 per cent of the total man-hours worked, and 77.45 per cent of the total ex-factory value of products and by-products of the 29 industries under the 1948 Census. As no census of manufactures existed in 1938 the author had to work on various assumptions, particularly with regard to the manpower requirements in 1938. According to his calculations the unit labor requirement index for 1948 is 111.28 (1938 = 100) and the index for total labor required to produce the current complex of goods with the unit labor requirements of the base period is 109.54 (1938 = 100).

Assuming that the author was successful in the various calculations in spite of the scarcity of data, it is doubtful whether the year 1948 should be used to compare the productivity of Indian industry with the prewar period. As the author himself points out, other important factors than labor productivity must be considered: there was hardly any replacement or modernization of equipment in the postwar years; the import of raw materials was irregular; the supply of electric power was often interrupted, and transport difficulties caused artificial scarcities of materials. All these factors, plus the inflationary

trend, were not conducive to an improvement in productivity. Even in various industrialized nations, productivity in the postwar years was lower than in the prewar period. Therefore, it would be very instructive to compare data for 1953 with 1938 and 1948. The more recent data would certainly supply a better basis for an assessment of productivity of Indian industry.

With regard to interregional productivity, twenty-four industries were examined. Productivity in the states with the greatest concentration of industries—Bombay and West Bengal—is about 8 per cent higher than in the rest of India. The reasons for that can be found in external economies and large-scale operations.

Balakrishna tried to compare productivity in various industries. He arrived at the conclusion that the disparity in productivity—in some cases very substantial—does not seem fully warranted by the differences in the capital equipment of the workers. Capital intensity in fact does not seem to offer any evidence for the differences in productivity. There also appears to be very little correlation between shifts in economic activity and productivity; perhaps profitability has been a more potent factor generating shifts in industry than productivity.

In the second part of the book the author analyzed most of India's industries and endeavored to provide data on output per man-hour, on capital equipment and kilowatt-hours per worker. Substantial differences are shown between the man-hours required in the same industry in various parts of India. The author also attempted to compare labor productivity over a period of time in cases where information was available. With the exception of the cement and match industries all industries show a decline in labor productivity. Again, the years taken as a basis for comparison cannot be considered normal.

Only in one industry, the cotton textiles, is an attempt made to compare productivity in India with that in other countries. The output of yarn per operative in India in 1947 was about 28 per cent of the output in the United Kingdom in 1937 and in Japan in 1933; the output of cloth per operative in 1947 was about one-half of that in the United Kingdom in 1937, and only about 30 per cent of the output in Japan in 1933. It would have been very useful to have similar comparisons for the steel and jute industries.

One finding which is common to most industries is very important. According to the author, a positive relation between capital equipment per worker and physical output per man-hour should be regarded as an exception. This may be a very important aspect of the structure of Indian industry. India has been known as the country of cheap and abundant labor and, for instance, its cotton textile industry has succeeded in expanding substantially its exports against industries with higher productivity of labor. At present, however, India is faced with new problems. It must develop new industries to provide employment for its growing population and must improve productivity of the existing industries. There is a strong tendency to protect the not very efficient cottage industry (for example, in cotton textiles) and to prevent reduction of the labor force which would result from the needed modernization. Production

costs are becoming more rigid. Furthermore, labor, now better organized and more influential than before the war, is pressing for higher wages, better housing, social security and other benefits. If labor productivity does not increase, India may cease to be a country of cheap labor. The problem cannot be solved, as the author suggests, by aiming "at economic development rather than at competitive efficiency." It is necessary to work out a policy suitable to the conditions of India which would make possible an increase in both production and productivity. Case studies on all major industries are needed which, together with other information, could serve as a basis for the government's industrial policy.

This book, which provides a wealth of information and in some instances offers recommendations as to policy, can be considered only as a beginning of the work to be done.

Washington, D.C.

Statistics and Econometrics

Business and Economic Statistics. By WILLIAM A. SPURR, LESTER S. KELLOGG, and JOHN H. SMITH. (Homewood, Ill.: Richard D. Irwin, Inc. 1954. Pp. xl, 579. $6.00.)

Any author of a text in elementary statistics for social science students, in addition to facing the usual chores of the textbook writer, finds himself confronted with a most difficult and delicate problem: the determination of content and level of the course for which his book is written. Since there has been less uniformity in the treatment of the introductory statistics course than of most any other part of the undergraduate social science curriculum, the textbook author also becomes, of necessity, a curriculum planner. Planning the curriculum and determining effective ways of providing the social science student with an adequate statistics diet, however, presents serious and controversial problems with which this review is not concerned.

The objective of the course to which the present textbook—a successor to Brumbaugh and Kellogg's *Business Statistics*—addresses itself is suggested by the authors in their preface: a book "designed for basic courses in statistics offered in departments of business, economics, and general social science" with stress on "practical business and economic problems rather than on theory, mathematical derivations, or statistical techniques as such . . . Basic English is used as far as possible in place of the polysyllabic jargon so common in technical publications, and the use of symbols and mathematical formulas is kept to a minimum."

Within the framework of these objectives the authors have presented a remarkably clear and simply written text. The first eight chapters deal with a review of arithmetic manipulations occurring in elementary statistical computations; with a well-documented treatment of sources of economic statistics, amplified by an appendix; with the collection of original data, including a nontechnical discussion of sampling designs and procedures; and with the

construction of tables and charts.

Chapters 9 to 11 discuss empirical frequency distributions and their descriptive measures; Chapters 12 and 13 are given to the construction of index numbers as well as to an up-to-date description of major economic indexes, and Chapters 14 to 16 treat the analysis of economic time-series. These 16 chapters occupy approximately 460 pages. The remaining eighth of the text discusses reliability of statistical measures and statistical quality control. The appendices include, in addition to the already mentioned carefully prepared and annotated listing of sources of economic statistics, the usual set of statistical tables.

The outstanding features of the exposition are its lucidity, its helpful use of well-chosen and timely illustrations, its stress on approximate and graphic methods, and the well-chosen structure and organization of the material, *e.g.*, the early introduction of the survey design problem. As might be expected from a triumvirate of experienced and practicing economic statisticians, the presentation of statistical techniques is successfully woven into the fabric of applications. Throughout the book the student is led from the specific problem to the general statistical recipe. Inasmuch as some might frown at such an approach as not sufficiently dignified, it might be pointed out that the more formalistic approaches in themselves are no guarantee against a "cook-book-like" treatment. The authors of the present text seem to have had this point well in mind, and as this reviewer sees it, perhaps too well.

The book should serve a very useful purpose as a none too technical introduction for students in schools of business administration and in economics departments. However, in view of their approach, as exemplified by the complete absence of any mention of probabilities, the authors' belief that "nevertheless, the treatment is precise enough to meet the needs of those who plan to become professional statisticians" seems, in these times, hardly justified.

National Income and Social Accounting

Realistic Depreciation Policy. A MAPI Study. By GEORGE TERBORGH. (Chicago: Machinery and Allied Products Institute. 1954. Pp. xxiv, 197. $6.00.)

Discussions of depreciation in economic literature have been concerned primarily with valuation (mainly original cost versus replacement cost). The allocation over time of the sum to be amortized has received less attention. Although the present volume deals with both of these problems, its novel contribution is that it demonstrates the coordinate importance of the latter.

The author believes that the straight-line method, now prevalent in the United States, results in serious underdepreciation, because it does not amortize capital values fast enough. He advocates depreciation charges which decline over the service life of capital goods, and consequently write off a larger proportion of total value in the earlier parts of service life. Although the two methods yield the same result over the entire lifetime of capital goods, the

latter will always result in higher current depreciation charges if the capital stock is expanding.

The assessment of the quantitative importance of the depreciation problem is advanced significantly by articulated estimates of depreciation charges for the U. S. economy under alternative accounting methods. The argument is logical and systematic. Speeded along at crucial points by a healthy ability to cut Gordian theoretical knots, it culminates in a set of practical recommendations for tax policy. The work, it may be added, is a masterpiece of exposition. It can be recommended to all those who take pleasure in craftsmanship.

Only brief comments on the significance of depreciation charges for the functioning of the economy are given (in Chapter 1). Inadequate depreciation is regarded as harmful because it tends to reduce investment by diminishing the supply of investment funds. (This comes about mainly because amounts that should properly be charged to depreciation appear as part of net profits and hence are taxed.) Possible stimulation of investment from the demand side by the concurrent overstatement of profits is not taken into account.

The analysis of depreciation charges in their bearing upon the functioning of the economy involves broad issues, such as the desirability of a high-investment economy and the availability of investment opportunities, which are outside the scope of this book. Earlier writings of the author (especially *The Bogey of Economic Maturity*) should be consulted for a statement of the economic philosophy which underlies his view of depreciation charges.

Highlights in the development of depreciation accounting in the United States, as influenced by the policies of the Internal Revenue Service, are given in Chapters 2 and 3.

The case for depreciation charges which decline over the lifetime of capital goods is established in Chapter 4. The basic reason for such a pattern is the decline in successive annual service values which stems from the mounting impact of wear and tear and obsolescence. The pattern of decline for depreciation charges advocated by the author is more moderate than that implied by the decline in service values, because future service values are discounted in his formula. In other words, service value used up in any one year is partly offset by the fact that future service values grow as they move closer to the present. This tendency is stronger in the earlier parts of service life when the stock of maturing unused service value is relatively large than in later parts of service life when this stock is smaller.

This use of a discount factor raises a problem of theoretical interest. To illustrate it, let us abstract from the influence of annual service values (available for capital recovery and profit, *i.e.*, receipts minus operating expenses other than depreciation) by supposing that they are constant over the lifetime of a capital good. Annual depreciation charges would then be increasing because of the operation of the discount factor, and the net output of the capital good would appear to be declining over its lifetime. To the present reviewer this result is not appealing if the aim is to gauge annual performance. On the other hand, the procedure does secure a constant annual rate of return on the

depreciated value of the investment, which seems reasonable from some other standpoints. By contrast, a calculation of depreciation charges which does not take into account the discount factor would indicate constant net output over the life of the equipment, but would show an increasing rate of return on investment. To this reviewer this presents a dilemma which he has not been able to resolve.

In Chapter 5 the allocation pattern derived in Chapter 4 is confirmed by data on the market values of second-hand durable equipment.

Lags in depreciation, resulting from the dispersion of actual service lives around the expected average on which depreciation quotas are based, are examined in Chapters 6 and 7. These lags are shown (in Chapter 8) to be of secondary importance to the deficiencies stemming from straight-line write-off itself.

Quantification of the deficiencies in depreciation resulting from present allocation methods is provided in Chapters 9 to 11. Estimates of this type are exceedingly difficult to make, because of data gaps; at the same time the work involved is prohibitively time-consuming unless one knows how to take short-cuts. Ingenuity and bold simplifications in procedure (such as the use of a rather simple weighting system for combining the average lives of different types of equipment; and the application of a constant life-dispersion pattern to annual increments of investment irrespective of their composition) enable the author to develop estimates that quantify separately most of the aspects of the problem with which he deals theoretically.

A check on the reasonableness of his results is provided by a comparison of depreciation charges as computed by him, assuming accounting methods now in force, and those actually reported on corporate tax returns. This check is not quite so satisfactory as is suggested by the author, and there appears to be some understatement in his estimates if, in deriving corporate from total computed depreciation, estimates for unincorporated business made by the U. S. Department of Commerce (but not available to the author when he wrote his book) are substituted for those he uses.

In discussing the valuation problem, in Chapter 12, the author pronounces in favor of revaluation to maintain the general purchasing power of depreciation quotas, rather than revaluation to make them sufficient to maintain the real stock of capital. Accordingly he is able to sidestep the difficult problems connected with the concept of keeping capital intact. Others, connected with the definition of general purchasing power (including selection of items, weighting, and quality change) he brushes aside with the remark that he is not after theoretical niceties, but "attempts to secure under conditions of inflation, the same results that conventional depreciation yields under stable conditions" (p. 119). Summary treatment of the major principles involved would be unsatisfactory in theoretical discussion, but is necessary if practical policy is to be formulated.

The extent of the total deficiency in depreciation on United States fixed capital, other than residential property, is summarized at the end of this chapter. Certain key figures are as follows. The current annual deficiency of

depreciation charges amounts to almost $7 billion, or nearly 50 per cent of the total now charged. About two-thirds of this is attributed to incorrect valuation, the remainder to incorrect allocation over service life. Future depreciation quotas on existing equipment are estimated to be deficient by about $70 billion in terms of 1953 purchasing power; and underdepreciation on existing equipment due to the use of deficient allocation methods is put at $30 billion.

In the opinion of the reviewer two major considerations should be kept in mind before these figures are taken as comprehensive measures of the underdepreciation of American productive capital. In the first place, as the author himself notes, no allowance is made for the fact that owing to technical progress depreciation charges tend to be overstated from the standpoint of maintaining productive capacity. A source of overdepreciation, probably huge, although it cannot be quantified, appears if maintenance of capacity is accepted as a criterion. Second, the estimates are based on average service lives specified by the Internal Revenue Service (in its Bulletin F). If service lives used for tax purposes (whether conforming to Bulletin F or not) should differ from actual service lives, there would be an additional source of under- or overdepreciation which is not quantified in the above estimates.

Advantages of depreciation reform are presented in Chapter 13. The total tax gain (due to the purchasing power adjustment for inflation) and the timing gain (due to an accelerated pattern of allocation) are considered, as well as more technical points such as the diminished risk of retirement losses not covered by taxable income.

Concrete proposals for tax reform are formulated in Chapters 14 to 16. The proposed purchasing power correction is a onetime adjustment to raise future depreciation quotas on existing assets to the present price level. A continuous adjustment for future changes in price level is not advocated, presumably because it would be administratively too cumbersome. With respect to allocation, the author advocates the declining balance method, at a rate double the straight-line rate, as a reasonably simple method for approximating the standards of allocation developed earlier in the book.

The immediate revenue loss from the full implementation of these two proposals would be substantial. To ease the transition, the deferral of the purchasing power adjustment is considered, and also a compromise between the straight-line and the double-rate declining balance method for a brief period. The limitation of the latter method to assets installed after a specified date is not favored.

In the final chapter the point is made that gross tax losses from depreciation reform will be offset by tax gains if they result in accelerated economic growth. Calculations are made which show net tax gains beginning about ten years from now. The author warns against a too literal interpretation of these calculations.

GEORGE JASZI

Washington, D.C.

Business Fluctuations; Prices

The Economics of Recession and Revival: An Interpretation of 1937-38. By KENNETH D. ROOSE. (New Haven: Yale University Press. 1954. Pp. xii, 280. $4.00.)

Professor Roose examines the recession of 1937-38, the most rapid in our history, and the revival of 1938, in an effort to test the major explanations that were put forward at the time, to test business cycle theory by empirical means, and to extract from the experience lessons that will be useful in our thinking about business cycles and government stabilization policy. The book is significant mainly, I believe, as an attempt to apply the historical-quantitative method of analysis. Careful analysis of the past offers one method for testing business cycle hypotheses but the analyst's path is beset with pitfalls. For this reason, such analyses need to be carefully examined.

In this case the author warns the reader of the limitations of the method: That hypotheses cannot be proved but only disproved and that where several factors are at work there may be no clear basis for judging their relative importance, so that if the analyst wishes to come to some conclusion he may be forced to rely partly on his "intuitive judgment." Since this judgment is almost certain to consist chiefly of his initial biases, Roose is to be commended for stating his bias explicitly. He also warns the reader when statistical data are lacking or inconsistent and tries to overcome some of these difficulties. Despite these virtues, the result cannot be regarded as a satisfying application of the method. The author sometimes forgets its limitations and those of the data in his desire to draw a conclusion where none seems justified by the evidence; he does not use all the data that are available, fails to consider some important hypotheses that were then or have since been advanced to explain the behavior of private investment in that period, and does not explore the possible relationships between the downturn and the preceding course of events which are suggested by modern dynamic business cycle theory.

After considering, in turn and separately, the causal role of a number of factors, the book concludes that the major causes of the recession were the drastic decline in the government's net contribution to income, which shifted the burden of sustaining income and output to private investment in an environment of depression-consciousness and uncertain expectations; Federal Reserve action, which at the same time increased the costs of capital; the undistributed profits tax which, besides adding to business uncertainty, reduced corporate liquidity; and, most important of all, the reduced profitability of investment beginning in the first quarter of 1937, which resulted from increased costs, including especially labor costs. Major, if not exclusive, credit for stimulating the revival is assigned to the government's spending program. The revival is not exhaustively dealt with, and the rest of this review is therefore confined to the author's analysis of the recession.

The sharp decline in the net government contribution to money income from a peak annual rate of over $5 billion in the middle of 1936 to zero or

a slightly negative figure in the middle of 1937 was clearly a factor in the recession, and the only difficult question, Roose says, is what position it occupies in the list of contributory factors. He concludes that it was not the "primary" cause, mainly because income continued to rise until September 1937, so that the decline in net government expenditure was felt, at most, only "indirectly"; and the lag between the turning points of the net contribution and total economic activity was too long to be accounted for by the time required for most of the multiplier effects to work. He also accepts, as true and inconsistent with a primary role, Slichter's conclusion that the flow of consumer goods did not out-distance consumer purchasing power, and believes that the cut in net contribution was somewhat less drastic than initial consideration of the data might indicate.

His conclusion appears to mean that the cut was not the immediate cause of the downturn or could not have caused it without affecting other elements of national product or expenditure. The data considered serve only to test this rather *simpliste* hypothesis of a direct effect of net contribution upon total activity. The author's reliance upon the time lag for the refutation of the hypothesis is based on acceptance of the view, which I thought had long since been recognized as fallacious, that the time period required for the multiplier to work, which relates to the ratio between *increments* of income and resulting *increments* of *expenditure*, is the same as the average income velocity of money, which relates to the ratio between *total* income and *total money supply*. The more important point is that, on a broader interpretation of the word "cause," the time lag is not a telling argument. The decline of income could have lagged behind the decline of the government net contribution by more than the consumption lag accounts for, if the latter decline had caused production that would otherwise have gone to consumers (and perhaps other final buyers) to go into inventories, thereby giving rise to an unplanned rise in the rate of inventory accumulation. If such a development had occurred while fixed capital expenditures or planned inventory accumulation (or both) were also rising, there would not necessarily have been a downturn in production, consumer income, or consumer expenditures until businessmen cut capital outlays or realized that inventories were accumulating more rapidly than they desired and reduced their orders. The timing of the downturn need have borne no close or direct relation to the timing of the decline in the government's net contribution. It may be only a matter of words whether one says that the downturn was "directly" caused by the decline in the net contribution or that it was "directly" caused by the decline in the rate of inventory accumulation. But since inventory accumulation above the desired rate would be caused, in this hypothetical case, by the curtailment of the government's net contribution, it would seem a normal use of language to say that the cut in the government's net contribution was a major cause, whether direct or indirect, of the downturn. My impression is that something like this may have been an element in what happened in 1936 and 1937. This hypothesis is not refuted at this point in the author's analysis or in the later discussion of inventories.

The author then turns to the Federal Reserve Board's actions in raising margin requirements on securities in February 1936, raising reserve requirements by 50 per cent in August 1936 and by another one-third in a two-step action in the first half of 1937, and the Treasury's gold sterilization action, begun in December 1936, which prevented incoming gold from increasing member bank reserves. The Board continued to advocate an easy money policy, professing to see no reason why its actions should affect this policy. Roose concludes that the Board's actions, especially in the spring of 1937, played a significant role in precipitating the recession, taking issue with Hardy, Schumpeter, Wilson, Slichter, and many others. These actions, clearly, raised the yield on short-term government issues and in all sectors of the bond market. Roose thinks that this rise of yields also led to the subsequent weakening of the stock market and made it harder to get new capital funds. Against Schumpeter's objection that "no business calculation can in practice be affected by so minute an increase" in interest rates, Roose surmises, on the basis of the rise in yields on common stocks, that the rise in costs of new capital for the average company may have been at least one-third, even though yields on *Baa* bonds rose only 10 per cent.

The analysis of credit policy appears sound as far as it goes but one misses an examination of its effects on residential construction and the relation between security issues and capital outlays. In appraising the monetary policies, Roose points out that restrictive measures were inappropriate when a substantial volume of resources was unemployed. He might also have pointed out that it was confusion to suppose that member bank reserves were "excess" in an economic sense merely because they were excess in a legal sense. Because inability to wipe out excess reserves (in the legal sense) does not necessarily imply inability to restrict credit, it was an error of analysis and policy for the monetary authorities to attach overriding significance to the *relation* between the government security holdings and the volume of excess reserves.

The role of price-cost relationships is examined to see whether a rise in prices relative to the wage element in costs reduced consumer demand by shifting the distribution of real income against wage earners, as some claimed, and whether a rise of costs relative to prices reduced investment by cutting profit margins, as others claimed. That a rise in prices relative to costs cut consumption in relation to income seems unlikely to the author. This conclusion rests mainly on the later examination of the view that the downturn resulted from a "failure" of consumption expenditure, meaning by this not an actual fall or a mere reduction in the rate of increase, but rather a decline in the relation of consumption to national income, while national income was still rising. Warning the reader of lack of comparability, gaps, and inconsistencies in the available statistical data, the author concludes that the recession was not due to a failure of consumption expenditure because consumer income kept up with production of consumer goods and consumer expenditure kept up with consumer income. The data he uses, however, show that production of these goods rose more than both deflated consumer income and expenditure between the 1st and 4th quarters of 1936 and fell by less than consumer

expenditure between the 4th quarter of 1936 and the 2nd quarter of 1937. The conclusion thus appears to rest heavily upon the fact that between the 2nd and 3rd quarters of 1937 the production of consumer goods declined very slightly (0.6 per cent) while deflation of Barger's series show increases of 6½ per cent for both consumer income and expenditure and the Department of Commerce series for consumer expenditure (not deflated) reached a peak in September 1937. These data lead Roose to the conclusion that the recession was not immediately preceded by a decline in the consumption function or in the marginal propensity to consume.

The main difficulty in the treatment of consumption is the failure to state clearly what hypothesis is being tested. Consumer goods output and consumer income are compared but it is not clear to what this is relevant. A direct comparison of consumer goods output with consumer expenditure on goods alone would be relevant to the inventory situation, but the author makes no such comparison. A comparison of consumer income and expenditure is only one element in the relation between consumption and total output. A comparison of consumer income with *total* output would be relevant to the other element in the relation between consumption and gross national product, but that he also foregoes. If the hypothesis being tested is that consumption stopped rising, the refutation is questionable because it is based on the rise of Barger's consumption series between the 2nd and 3rd quarters of 1937. Roose gives no evidence of having noticed Barger's warning that his quarterly figures for consumption of perishables include changes in distributive inventories.[1] While Barger's series rises 7 per cent between these two quarters, the Department of Commerce series for total consumer expenditure rises by only 1 per cent, barely but not significantly more than the National Industrial Conference Board cost-of-living index. This raises a question whether total real consumption rose at all after the 2nd quarter. It may be noted that between the 4th quarter of 1936 and the 2nd quarter of 1937 the Barger series falls 2 per cent while the Department of Commerce series rises 5 per cent. These differences, combined with the known inclusion of changes in inventories of perishable goods in Barger's consumption series, should make one wary of using it as the basis for conclusions about short-period movements of consumer expenditure.

Turning to private investment expenditures, Roose shows the importance of inventory investment and the incompleteness of the recovery of fixed capital expenditures. (He uses only undeflated dollar figures and makes comparisons only with 1929, thereby exaggerating the failure of the recovery.) He believes that in the summer of 1937 the rate of inventory accumulation shown by Barger's figures was excessive in relation to new orders, which declined substantially during the summer, but was not unreasonably large in relation to income, production or consumer expenditures. Roose believes this view is confirmed by Metzler's conclusion that the *level* of inventories was not large in relation to net national product, and refers to this conclusion as "much

[1] Harold Barger, *Outlay and Income in the United States, 1921-1938*, Studies in Income and Wealth, Vol. 4 (New York, 1942), p. 95n. See also p. 95.

the same" as Slichter's conclusion that the *change* in inventories was not dangerously out of proportion to the change in industrial production. He states that a considerable part of inventory accumulation was the unplanned result of the downturn of income, expenditure and production, and concludes that it was an intensifying but not a causal factor in the recession.

Roose gives no reasons that are relevant to the negative part of this conclusion. That the *level* of inventories would not have been burdensome without a decline of national income or expenditures may be true but it proves little about the causal role of inventories. The belief that it does ignores the fact that a mere reduction in the rate of accumulation, which can occur even before the *level* of inventories has reached the level business wants to hold, is a depressing influence. The cautious statement that inventories were "more resultant than causal to the extent that they accumulated because income and expenditures declined" (p. 189) does not answer the question whether they *were* causal to the extent that they accumulated *before* income and expenditures declined. The significant question is when inventory *investment* (not inventories) reached a peak. Barger's quarterly figures, which include only manufacturing and distribution, show a pronounced peak for inventory investment in the third quarter of 1937, but there are reasons for doubting their reliability as an indicator of *total* nonfarm inventory investment. The annual total for manufacturing and distribution inventory investment rises $500 million between 1936 and 1937. Although Abramovitz' figures appear consistent with this, Barger's own annual series for *all* nonfarm inventory investment falls $189 million and the Department of Commerce series falls $350 million. Barger himself says "the very large increase in inventories in the third quarter of 1937 is difficult to credit."[2] The conclusion Roose draws from other data, which gives him greater faith in Barger's series than Barger has, relates to the level of inventories, not inventory investment, and is therefore irrelevant. The whole discussion of inventories, in fact, is marred by confusion between the level and the change of inventories. Sometimes only the language is careless, the meaning being clear (*e.g.*, p. 184, note 1), but too often the confusion is substantive.

Roose's standards for testing whether the rate of inventory accumulation was excessive are the ratios of this rate to the rate of change of output and to the level of new orders, compared with the corresponding past "normal" ratios. Such a ratio will always be deceptive when accumulation of inventories is still a significant component of output. As dynamic business cycle theory suggests, if inventory accumulation is to be regarded as excessive only when it exceeds a certain proportion of the growth of output, the growth of output used to test it must be a sustainable one; it cannot be merely whatever rate of change in output happens to prevail. Observation, too, suggests that the stability of an economic expansion as rapid

[2] *Ibid.*, p 312; cited by Roose, p. 184. Abramovitz, writing later, says about the general question of the time relationship between the downturn of inventory investment and that of demand for other goods: "Were adequate monthly data available, this issue could be settled; but . . . in their absence the facts remain in doubt." (*Inventories and Business Cycles*, [New York, 1950], pp. 497-98.)

as that which occurred in the second half of 1936 and early 1937 is always suspect, for it nearly always includes a large element of inventory accumulation, and a rate of inventory accumulation much in excess of the requirements for long-run growth is always likely to involve instability unless it is set off by expectation of an interruption of external supplies (*e.g.*, war, blockade) or an expansion of final demand *which proves to be correct.* The monetary authorities may have had a sounder instinct than the author if, notwithstanding their publicly expressed views that no injurious credit expansion had yet occurred and that their actions were merely preventive, they actually felt that the very rapid expansion involved dangers despite the presence of unused resources.

In considering the reasons for the fall of fixed capital expenditure, Roose is impressed by data showing that profits may have begun to decline after the last quarter of 1936 and certainly declined after the 2nd quarter of 1937. Average hourly earnings in manufacturing and the average of all wholesale prices rose by roughly equal percentages from December 1936 to March 1937, but between March and June of 1937 hourly earnings rose by 5.7 per cent and wholesale prices declined slightly. Roose concludes from the profits data that the profitability of investment declined while the demand for goods was still growing and that the rapid rise of costs contributed to the recession through disturbing the prospects for profits. The conclusion is first stated cautiously: "insofar as developments in these specific areas [the railroad, building, and electric power industries] may be generalized, and to the extent that investment expenditures were reduced by the prospect of declining profits, the rise in costs reinforced the recessive tendencies" (p. 141). Although no statement is made as to how far these developments may in fact be generalized (beyond excluding the textile and rubber tire and tube industries) or to what extent investment expenditures were reduced by the prospect of declining profits, the author later forgets his caution and indicates belief that a decline of profit prospects (independent of the recession itself) did reduce investment expenditures. Apart from the reversal of profits, he also believes that the level of profits during the whole recovery period was "beyond question" inadequate to stimulate any sizeable expansion in long-term investment commitments. Roose agrees with those who attributed this longer-run situation to business uncertainty over future developments, the increase in the level of individual income taxes after 1934, especially taxation of capital gains, threats of government competition with the public utilities industry, and other political, social and economic factors which raised doubts about the future in the minds of business men, rather than to an absence of investment opportunities.

How sure can we be that profits began to fall while the demand for goods was still rising and that they were dangerously low throughout the recovery period? And how well does this explain the failure of private capital expenditure to recover fully? The only available quarterly data for profits are Barger's, who interpolated from a sample of 700 to 800 corporations which excluded both wholesale and retail distribution as well as finance. Barger's figures decline less than one-third of one per cent from the last quarter of 1936 to

the 1st quarter of 1937 and a further 4 per cent to the 2nd quarter. Although Roose expresses doubt in some places as to the statistical significance of the first decline, and in his summary chapter says, "It does not appear likely, therefore, that the turning point [of profits] was actually reached until the second quarter of 1937" (p. 240), he several times (*e.g.*, pp. 25-26, 204, 225) refers to the cyclical peak of profits in the last quarter of 1936 as though it were an established fact. As the author clearly recognizes in his more wary moments, a decline of less than one-third of one per cent in such a series should be entirely ignored. Although one may conclude that the last quarter was the peak for railroads and communications, for which Barger had good coverage, the manufacturing component of his series reached its peak in the 1st quarter of 1937, mining and public utilities reached theirs in the 2nd quarter, and "other non-manufacturing" reached its peak in the 3rd quarter. Barger's series can be compared with the more comprehensive annual series of the Department of Commerce. Between 1936 and 1937 his series rises from $3.5 to $3.6 billion, while the current Commerce series (also after adjustment for inventory revaluation and income taxes) rises from $3.5 to $4.7 billion. This comparison suggests that Barger's figures understate profits in 1937 in relation to 1936 and that the peak of profits may have been in the 1st or 2nd quarter of 1937. Since the National Bureau of Economic Research places the peak of the cycle in May 1937, we can hardly be sure that total profits began to fall while the demand for goods was still rising. It is still more questionable that they began to fall sufficiently before the peak in the demand for goods to have had effects on capital expenditures large enough to cause the downturn in that demand.

The conclusion that the level of profits was dangerously low during the whole recovery period is supported only by showing that undeflated dollar profits "at their peak in 1936" were 22 per cent below their 1926-29 average and by citing Crum's comparison of "profit rates" (ratios to what is not stated) in 1936 with those of the 'twenties. (The author uses and attributes significance to undeflated dollar figures not only here but in several other places in the book, although prices in 1936 were much lower than in 1929.) Even an adjustment of profits proportionate to prices would understate 1936 "real profits" since it would not fully take into account the lag of the depreciation deduction behind the price level. Moreover, Crum's figures stop in 1936, which was not the peak of the annual figures. Further, reference to Crum's article shows that the figures Roose cites relate to rates of total return (including investment income) after taxes on total equity after taxes; they do not show profits from operations. As Crum himself points out, "the rate of return on direct equity is definitely a better measure of the earning power of the corporate enterprise considered as a productive operation."[3] Crum's figures for all nonfinancial corporations show that, while the total rate of return on total equity fell from 6.84 per cent in 1929 to 5.24 in 1936, the rate of return on direct equity fell by much less, from 5.94 to 5.13 per cent. For manufacturing alone, the only industry division for which Crum shows both

[3] W. L. Crum, "Cyclical Changes in Corporate Profits," *Rev. Econ. Stat.*, (May, 1939), XXI, 61.

rates, the rate on total equity fell from 8.64 per cent in 1929 to 7.94 in 1936 but the rate on direct equity rose from 8.26 to 8.39 per cent, despite the fact that 1929 was a very high year, and 1936 was not the peak year of the recovery. Thus doubt is cast on Roose's conclusion by figures in the very article he cites as evidence.

The evidence is that the post-1933 recovery was not a "profitless prosperity" generally, although it was for a few sectors of the economy. The Department of Commerce figures for profits, which unfortunately begin with 1929, show that in 1936 and 1937 the big deficiencies in profits were in "finance, insurance and real estate" and in railroads. In the aggregate of other fields, profits appear to have been substantial if one allows for the height of the 1929 base and the lower level of prices. Here are the undeflated figures after taxes, both including and excluding inventory revaluation:

	Million Dollars			Per Cent of National Income		
	1929	1936	1937	1929	1936	1937
Including inventory revaluation:						
All corporations	8,420	4,273	4,685	9 7	6.5	6.4
Finance, insurance, real estate and railroads	1,634	−240	−39	1.9	def.	negl.
All other	6,786	4,513	4,724	7 8	6 0	6.4
Corrected to exclude inventory revaluation:						
All corporations	8,892	3,535	4,654	10 2	5.5	6.3
Finance, insurance, real estate and railroads	1,639	−248	−63	1.9	def.	negl.
All other	7,253	3,783	4,717	8 3	5.8	6 4
Implicit GNP price deflator (1939=100)	120.9	98.3	102.7			

The failure to use up-to-date profits figures, to use a figure for profit from operations, to allow for the greatly reduced price level, to examine the figures for individual industries and to see how profits of individual industries relate to capital expenditures by these industries, to consider rates of returns in relation to interest rates are serious defects in the statistical part of the argument relating profits to capital outlays.

The author also appears to assume that the *actual* current profitability of the *total* capital stock and the marginal efficiency of investment, which is *subjective* and relates only to the return on *additions* to the capital stock, are the same thing. The two are of course quite different, although they appear to be highly correlated. If one could rely on such a correlation holding at all times, the theoretical confusion itself might not cast doubt on the conclusion about the decline in the profitability of investment, but in 1936 and 1937 it is a question whether one can rely on it. The argument implicit in Currie's Tem-

porary National Economic Committee testimony and explicit in Taitel's TNEC monograph[4] was that current operations might be highly profitable but, with substantial capacity remaining unused, additions to capacity might be unprofitable. This is just one of many factors that might make profits from current operations a poor index of the marginal efficiency of investment. Roose mentions Taitel's argument as an alternative explanation of why construction expenditure was low but never discusses it. He gives no consideration to the related hypothesis of Smithies' valuable paper on "The American Economy in the Thirties," Lawrence Klein, on whose work Smithies drew, or of Gordon, that the stock of capital equipment built up during the 'twenties played an important role in depressing investment in the 'thirties.[5] That some factor besides the level of current profits is required to explain the low level of capital expenditures at that time would have been clear if the author had examined the relation of profits to capital expenditures by industries. He would have found, for example, that for "retail trade and auto services" dollar profits were nearly as high in 1936 and 1937 as in 1929 and deflated profits were higher, but even the dollar volume of new construction by the corresponding category ("stores, restaurants and garages") was less than half of the 1929 level. The same general relation holds for farm net income and new construction. No explanation is offered of the incompleteness of recovery in residential construction, although the government's attitude toward business and the level of business profits could hardly have been a major factor in this field. The failure of recovery in private construction was more pronounced in the area labeled "religious, educational, hospital and institutional and miscellaneous" than it was even in railroads. How is this to be explained? Besides failing to consider the excess-capacity explanation of low business capital outlays, the author does not consider the 60 per cent decline in the rate of population growth from an annual average of 1.7 per cent in 1920-25 to one of less than 0.7 per cent in 1930-35. In fact, I believe that there is no reference to population or its rate of growth in the entire book, apart from a passing reference to the evidence of economic maturity which Hansen gave.[6] Whatever the reason for the failure, the autonomous elements in con-

[5] *Am. Econ. Rev, Papers and Proceedings*, May 1946, XXXVI, 11-27; also A. H. Hansen and R. V. Clemence, ed., *Readings in Business Cycles and National Income* (New York, 1953). This paper covers the 1937-38 cycle and takes a position very different from Roose's on several essential points, but Roose does not refer to it. L. R. Klein, *Economic Fluctuations in the United States, 1921-41, passim* and especially p. 124; and R. A. Gordon, *Business Fluctuations* (New York, 1952), pp. 397-98, and also "Cyclical Experience in the Interwar Period: The Investment Boom of the '20s," in *Conference on Business Cycles* (New York, 1951), pp. 204-6.

[6] The fact that construction was rising substantially when the downturn occurred, but from a very low level, raises still another possibility: whether the failure of construction to reach 1929 levels might be accounted for by the depth of the trough combined with mere lack of time before interruption by a recession originating in other areas or by higher interest rates.

struction demand were clearly weak and the question is, Why? One is forced to conclude that the author's preference for one or two among several possible explanations, most of which he does not examine, has no clearly discernible basis.

At many points in the book it is not clear how basic a meaning the author attaches to the word "cause." For example, his conclusion about the decline of the government's net contribution is stated in a variety of ways that seem to imply it was not a very important cause of the recession. Thus, it was not a "primary" cause (p. 71); not the "direct" cause (p. 77); only "indirect at most" (p. 71); "overrated as an explanation" (p. 77); not the "principal reason for the later decline in income" (p. 77). But the author also says that the reasons for this conclusion do not answer the question "whether the recession would have occurred had the net contribution remained at a substantial level" (p. 77). This more basic question is treated inconclusively in a few sentences. Elsewhere it is repeatedly assumed that the 2nd and 3rd quarters of 1937 are the "crucial" or "vital" periods. This assumption seems to suggest a failure to appreciate that a downturn could be caused by prior events acting in an economy with given responses, combined with a failure of policy either to introduce new autonomous factors or to alter the economy's responses. There is an artificiality in considering various elements of the situation separately without considering fully their relationship to each other, *e.g.*, the relation of the cost rises to the rise in inventory accumulation; of the latter to the time lag between the decline in net contribution and the downturn of production, and to the increased demand of corporations for external funds; the effect of changes in availability of money on residential construction and many other interrelated factors.

The main conclusions about analysis of cycles that I draw from the book are a further confirmation of what modern cycle and econometric theory tell us, namely, that the main elements making for a downturn may not be found in the period during which it occurs, and that progress in analysis of a specific cycle or in empirical testing of hypotheses requires fuller statements of the hypotheses to be tested, examination of all of them, and considerably more disaggregation of the data.

International Cycles and Canada's Balance of Payments 1921-33. By V. W. MALACH. (Toronto: University of Toronto Press. 1954. Pp. xii, 154. $3.00.)

This book is the first volume in a new series of Canadian Studies in Economics. The series is off to a good start. Professor Malach has given us a careful scholarly survey of the Canadian major cycle of 1921-33 with particular reference to the theory of the spread of international cycles and the cyclical aspects of balance-of-payments adjustments and capital movements. After an initial brief survey of business cycle theory the book devotes separate chapters to the three cyclical turning points and to the upswing and downswing of

the cycle. Separate attention is given in each chapter to domestic and international aspects. In a concluding chapter the empirical findings for the period as whole are used to test the applicability and consistency of the theories outlined in the first chapter. The book is an excellent example of the objective use of statistical material to test prevailing theories.

The outline of cycle theory seems to follow that set forth in Haberler's standard work with separate attention being given to the monetary, the monetary overinvestment, the nonmonetary undersaving and the underconsumption theories of the cycle. Malach's outline of the international aspects of these theories seems a little forced since many views on the international aspects of cycles are not clearly related to any of the above theories. But this is not too serious, and the literature on international cycles is thoroughly surveyed either in the initial or the final chapter. No explanation is given as to why this particular framework of cycle theory was adopted or why, within this framework, some writers, such as Cassel, were given more attention than others, such as Schumpeter.

A number of Malach's findings are of interest. Thus he shows that cyclical turning points in Canada, a country highly dependent upon international trade, have sometimes preceded and sometimes followed those of more highly industrialized countries. Further, cyclical movements were in some periods less intense and in other periods more intense than those prevailing elsewhere. Thus the economic upswing in Canada was much weaker than that in the United States and in many other countries from 1921 to 1925 but became much stronger in the latter part of the upswing from 1926 to 1929. International trade specialists will be particularly interested in the analysis of capital movements and the mechanism of adjustment given in the final chapter. Both capital movements and the balance on current account were determined primarily by the relative strength of cyclical movements in Canada and elsewhere, it is suggested, and as a result Canada experienced comparatively little balance-of-payment difficulty during this period despite the rather wide swings in her capital movements and her current exports and imports. The irregularity that at times appeared in the flow of long-term capital is explained primarily by the uneven pattern of government borrowing and the bunching of redemptions.

While in the main statistical data are used with due regard to their limitations there are a few instances where the author places more confidence in his data than they really warrant. Thus it is doubtful if the discussion of changes in the propensity to save in the early 1920's, based as it is on unpublished data of doubtful accuracy, can be taken at all seriously. Further, the reader should be warned that the national income data used are based on the old Kuznets' definitions with their curious concept of government profits and losses. And though the author uses his data with care the reader might easily overestimate the representativeness of the seventy series which are used to establish cyclical turning points. In fact, in the index of industrial output from which many of these series are taken, data on the volume of output provide reasonable coverage for less than 25 per cent of the net value added

by manufacturing in 1929. However, these are but minor defects in what is basically a good piece of work. Inclusion of a chart or table on exchange rates would have been helpful to the reader.

C. L. BARBER

University of Manitoba

Business Cycles. By EARL C. HALD. (Boston: Houghton Mifflin Co. 1954. Pp. xvi, 518. $5.00.)

In the preface the author states that "this book is intended . . . for the standard course in business cycles . . . in the third or fourth year" of college . . . and that "it does not presuppose . . . an extensive acquaintance with economics." The objective is "to furnish students a minimum background . . . in the study of cycles."

Part I, 110 pages, deals with "the nature of economic fluctuations"—their statistical behavior; incomes and expenditures; and the history of business cycles in the United States. These materials are well organized and controversial issues are held to a minimum. The presentation is supported by numerous diagrams and tables; and so is the historical report which deals mainly with events since 1900. The addition of a discussion of output and prices during the nineteenth century would have added to the understanding of the long-time record of historical tendencies. Except for this omission this introduction to the dynamic character of the economy is well done.

Part II, a survey of cycle theories of about 100 pages, draws ideas from more than forty authors. The presentation would have been improved by rendering a straight-forward statement of each theory without discursive comments. For instance, there is no point in berating the early classical economists for not engaging in the study of business cycles (pp. 114, 216-17). Neither Adam Smith nor Ricardo "ignored or were unaware" of trade fluctuations. They were neither unempirical in their approach nor unstatistical within the limits of existing data and statistical techniques. They spared no effort to diagnose the consequence of bad public finance, of bad banking, of foreign exchange and inflation.

Part III, 158 pages, discusses critically the essence of cycle theories. It covers turning points, money elasticity, savings-investment and income level, consumption and investment, international aspects, and business and economic forecasting. The handling of these materials is verbose to an extent that impairs its effectiveness. The analysis of turning points, which involves the ideas of more than ten theorists, is particularly difficult to follow. The statistical data might well have been preceded by a more extended presentation of principles in order to lend them significance. Perhaps this was not done because these data are not adequate for support of the theories; but neither are they adequate for the purpose of drawing general deductions. Again, on what a theorist holds to be the main issue and what the side issues, greater care was warranted in order to render the account correctly. For instance, I do not believe that Schumpeter would have relied upon "a new swarm of innovators to come along at just the right time . . . when a depression has run its course."

Nor would he have agreed that his theory has "no firm foundation for a theory of recurrent booms" (p. 285). Schumpeter held that development proceeded by discontinuity; that the rallying of the economic system is preceded by resorption and reorganization of its values; and that partial developments may coincide with total development.

The analysis of a country's economy in the adjustment from a capital-importing to capital-exporting position is not clear (pp. 315-16). It is not a problem of differences and/or shifts in respective price levels, no matter how it is considered. The shift of capital has to do with profitability of development, opportunity cost, and comparative cost. It is not true that "Britain sold a large part of her foreign investments" during World War II and that her economic troubles are to be attributed to this and to foreign debt incurred (p. 316). Britain sold 27 per cent of her foreign investments and probably only those for which there were impetuous buyers. As John Jewkes has said, the reduction of income from foreign investments "is insignificant in relation to the real difficulties of the nation" (*Ordeal by Planning*, 1948, p. 215). There is, I think, an error in the computation of the sterling-dollar purchasing-power parity (p. 313). The answer is $9.72, not $2.43.

If I am not mistaken about the caliber of the student who may be expected to dig into the many controversial propositions in Part III, which includes a brief account of the Hicksian model, there will be a lot of gasping. A better job could have been done with a substantial addition or substitution of the Mitchell-Burns approach. That approach does not receive enough attention.

Part IV, on the control of business cycles, 126 pages, discusses policies, monetary and spending, wages and prices. There is here all that one might ask for about disagreements, dilemmas, moral suasion, stimulators, panaceas, and deadlocks. The author favors more built-in stabilizers, and greater activation of industrialization abroad in the event of a decline in the demand for capital at home.

It is my impression that this book will not serve the purpose for which it was designed. The student who does not have "an extensive acquaintance with economics" will find it difficult to handle and the unwary student will get the impression that the analysis of the cycle is a manipulation of concepts.

Money and Banking; Short-Term Credit; Consumer Finance

How Money Is Managed: The Ends and Means of Monetary Policy. By PAUL EINZIG. (Baltimore: Penguin Books, Inc. 1954. Pp. 368. 65c.)

Paul Einzig is a very facile journalist-economist who has a rare faculty of making controversial issues and even technical economic problems understandable, not only to the specialist, but to the average reader of newspapers. This—the latest of his forty-odd books—is an interesting semipopular-semischolarly survey of the monetary system, the changing emphasis which has been given to the role of money in social welfare democracies, and the ever

widening variety of means used in influencing economic, social, and political trends.

Part I of the four parts presents a brief outline of the monetary system, a description of the British system as it now operates, and the author's rather broad conception of what is meant by monetary policy. Part II is concerned with the objectives of monetary policy. With sympathetic acceptance of the Knapp "state theory of money" thesis that "money is the creature of the law," he traces the many ends to which official effort may be directed in order to increase the advantages of the monetary system to society or to reduce its disadvantages. We find chapters on the pursuit of internal and external stability, the policy of raising prices, raising the value of money, accumulating and safeguarding monetary reserves, influencing foreign trade, fiscal objectives, mitigating business cycle fluctuations, full employment, social, political, and other objectives.

Part III deals with the means of implementing policy. All manner of devices are discussed, both new and old. The author devotes aggravatingly short chapters to intriguing subjects: The volume of money or credit is increased or decreased to stimulate business or to step up the pace of the development of the welfare state on the one hand or to check inflationary tendencies on the other. Various categories of borrowers, such as consumers, investors, speculators, buyers of real estate, and export industries, are discriminated against by means of selective credit controls. The level of interest rates is controlled. The budget is deliberately unbalanced in order to expand purchasing power (see page 247 for a neat treatment of Keynes's "theoretical foundation for the new policy"). Taxation is used for discouraging certain types of spending. A variety of treasury fiscal devices are employed, not only to influence the volume of bank credit, but also to increase or reduce banks' cash holdings and liquid assets. Even the velocity of circulation has come within limited control. The author describes in a very interesting manner how in the 'thirties the governments of the United States and elsewhere, deciding that the increase in the mere volume of money had proved futile because people refused to use it, attempted to substitute government spending for private borrowing. Pump-priming operations were initiated on the theory that "if business won't, the government will." In another chapter, the author distinguishes between the quality or buying capacity of money and its purchasing power. Here he makes a case for self-liquidating credit transactions and warns against inflationary unproductive government expenditures and frozen credit. Even price control (rationing by coupons rather than by purse), wage ceilings and minimum wages, rent control, government trading, and other direct methods of government intervention to determine the volume and nature of production and distribution find a place in Einzig's conception of monetary policy. Two chapters are devoted to foreign exchange policy and exchange restrictions and their relationship to domestic welfare.

The conclusions (Part IV) contain an effective appeal for international cooperation which would coordinate domestic monetary policies. The European Payments Union is a step in the right direction and the eventual restoration

of sterling convertibility would be another, but these do not satisfy the author, for, he says: "Even though it may take generations before the ultimate end of the creation of an international currency can be achieved, the progress made in that direction in the past quarter of a century justifies hopes that it will continue" (p. 352). Part IV also contains some interesting observations drawn from recent experience on the role of economists and the reconciliation of theory and practice in determining policy. The book closes with a chapter on the future of monetary policy.

Einzig's credo may be briefly stated as follows: Money has always been managed in the sense that the government is responsible for money functioning at all, but in recent years money management has transcended the traditional role of maintaining a stable standard of value and a medium of exchange through which the price mechanism operates and has become an engine of social reform. The author claims to take a compromise position between the views of extremists, but in effect he leans heavily toward the welfare monetary school, although he does this not with the buoyancy of a reformer but with a tired air of resignation as if he had reluctantly capitulated to the inevitable. For example, he says: "Given the facts of universal suffrage and the menace of Communism, it has become politically impossible to revert to a monetary policy that would disregard considerations of social welfare, even if we wished to do so" (p. 10). With illustrations drawn from the experience of many nations, he attempts to show the disadvantages of inaction with respect to money policy and the benefits derived by utilizing all of the old and many new means of managing money "to achieve the highest degree of welfare for the largest number, if necessary even at the cost of sacrificing stability. Indeed, if the economic requirements of higher productivity come into conflict with the social requirements of equalitarianism, the chances are that as often as not the latter will prevail" (p. 347).

There may be extremists who will find Einzig's compromise views inadequate in bending monetary or economic considerations to social aims, but the whole temper of the volume seems to this reviewer to reflect a willingness to sacrifice a stable standard of value and a sound medium of exchange to promote what might prove to be fictitious welfare. No classical or orthodox monetary economist would want to disregard considerations of full utilization of the country's economic resources and labor force and equity in income distribution, but to the traditionalist, capricious manipulation of the length of the monetary yardstick and the use of government fiat in determining money values do not seem the most promising methods of attaining those ends. Although Einzig does make many reservations and qualifications, the reader, on balance, gets the impression that never-ending prosperity and optimum social welfare by government fiat are attainable and that it is not a mirage, if only the "scientific" money managers learn to conduct their business properly and with balanced self-restraint (see, for example, pages 10, 21-22, 25, 33, 38, 53, 86, 89, 91, 136, 154, 203, 348, 350-351). To the reviewer, this view seems extreme.

The fact that this book appears for the first time in the Penguin series and

is sold at a modest price (one-tenth of what one usually pays nowadays for works of this character) should not deceive the reader. This book is a serious work and should be taken as such by students of the subject; it will have a wide public reception, which it deserves. It could even appropriately be selected as a text or as collateral reading. It includes five pages of bibliography, with a suggestive and useful selection of titles, new and old. The student as well as the general reader will find substance and enjoyment in this volume.

Public Finance

British Public Finances: Their Structure and Development, 1880-1952. By Ursula K. Hicks. (New York: Oxford University Press, Home University Library. 1954. Pp. viii, 225. $1.00.)

This small book supplies that blend of "learning with lucidity" which is a major aim of the editors of the Home University Library. The events of seven decades of British public finance are skillfully selected and woven into an interesting and thought-provoking narrative. One evidence of the magnitude of the task of compression and selection is to be found in Mrs. Hicks' earlier statement in the preface to her *The Finance of British Government, 1920-1936.* There she mentions the need of explanation and apology for the attempt to include sixteen years of British public finance within a single volume. The fact that she is able also to write the kind of a book which treats over four times as many years in about half as many words is evidence of her versatility and her knowledge of the field.

The book has six chapters which take up, in this order: the growth of public authorities, the forms of public expenditure, the adjustment of the tax structure, local government and the fiscal system, budget balance and national balance, and loan and debt management.

Much of the material could be adapted, with different illustrations and emphases, to apply to the United States and other democratic countries. Public authorities have expanded and their activities have become more centralized. The decline in the range and interest of local activities is making it more difficult to interest able people in taking on local responsibilities. Taxes on income and capital have increased both absolutely and relative to other taxes. This increase has been less in Great Britain than in the United States because of the wide scope and high rates of the British purchase tax. Nevertheless, the author believes that, as a consequence of direct taxation, personal saving has "virtually disappeared" (p. 28) in Great Britain. This means that government must fill the gap either directly or through tax concessions to firms.

The discussion of public expenditure is centered on social expenditure and "the re-establishment of economic activities and policy as an accepted function of the state" (p. 30). Expenditure on defense is mentioned briefly and then dismissed as a "technical matter" (p. 30). The activities of the state in respect to economic policy are emphasized throughout the book, with the

expenditure and revenue aspects brought together in Chapter 5: "Budget Balance and National Balance."

It would be out of order to note any sins of omission in view of the prescribed brevity of the Home University Library series. Since so much had to be left out this reader begrudged the allocation of ten pages in the last chapter to Dalton's debt policies which are described as partly a result of a "personal idiosyncracy" (p. 200). In this chapter, to the American reader at any rate, the developing relationships between fiscal policy and monetary and debt policy seem to be overshadowed by material of a more ephemeral nature. The considerable use of alphabetical designations (B.E.A., N.D.C., P.A.C., P.A.Y.E., etc.) puts some strain on the interpretive powers of the non-British reader. In most cases, however, the context supplies the clue and the essential points are clear. Clarity, in fact, is an outstanding characteristic of the volume.

LUCY W. KILLOUGH

Wellesley College

Program Budgeting: Theory and Practice. By FREDERICK C. MOSHER. (Chicago: Public Administration Service. 1954. Pp. xiii, 258. $5.00.)

Whether in private business or government, the budget is a basic instrument of financial control. Because of the magnitude of its expenditures and the complexity of its operations, the author directed this study primarily to the Department of Defense, with special concentration upon the Department of the Army. Unlike the traditional approach, this inquiry is an attempt to merge the two areas of public budgeting and military administration. Emphasis is on the central budget process, but some attention is given to such related subjects as military planning, unit equipment requirements, manpower control, procurement and personnel systems.

The content of the volume attests to the exhaustive study and thorough preparation which preceded its writing. After gleaning everything of value from published and unpublished documentary sources, the author had personal interviews with a large number of military and civilian employees within the Department of Defense and its three subdepartments and with well-informed persons outside the military establishment. Because of the heavy reliance upon personal interviews with experienced practitioners, the book has a freshness and an authoritativeness often lacking in studies of its kind. What might otherwise have been tedious and dry is interesting and stimulating, although by no means light reading.

The first chapter contains an introductory discussion of the purposes and principles of public budgeting. It dwells upon the factors that make up the environment in which national budgets are developed and administered. These include the time factor; organizational and institutional factors; personal factors; and political, social and economic forces. Chapter 2 is an account of the development and setting of military budgeting with special reference to the war period and unification of the armed services. Changes of a procedural and substantive nature are considered along with the effects of the astronomical increases in the defense budget.

The characteristics and interrelationships of plans, programs, and budgets are treated in the third chapter. It is pointed out that the development and implementation of military plans and programs are essentially functions of central military command and staff. The budget process, on the other hand, is oriented towards the Congress. Budgeting is related to programming in various ways, but the processes are basically distinct. A discussion of planning by the Joint Chiefs of Staff is followed by a critical analysis of the Army and Air Force programming systems. It is observed that the planning and programming systems of these services are still, in large part, hopes and plans.

Chapter 4 examines the extent to which the planning and programming systems have been integrated into the pattern of budgetary administration. Performance budgeting is treated at considerable length and special emphasis is given to the difficulties in applying this technique to military expenditures. One of the major problems is the increasing importance of long-lead items in military activities. Probably less than half of the funds appropriated to the Army for fiscal year 1953 were for the support of operations in that year, and the proportion for the Air Force was even smaller. Much of the budget is thus beyond recall. Suggestions are made for alleviating the problem, but no simple or easy solution is available.

The salient features of internal budgeting operation are sketched in the fifth chapter and the principal problem areas are singled out for particular attention. The author comes thoroughly to grips with the details and problems of internal budgeting. No attempt is made to treat procedures relative to the budget and appropriations in the Congress. A final chapter deals with the functions and responsibilities of military comptrollers and their relationship to the budget.

This meaty book is a valuable contribution to the literature of public budgeting. It is not intended to be a textbook, but it can be read with profit by all serious students of the subject and with particular value by persons both inside and outside government concerned with planning, programming, and budgeting.

International Economics

An International Economic System. By JACQUES J. POLAK. (Chicago: University of Chicago Press. 1954. Pp. xi, 179. $4.75.)

This small volume is divided into two sections. In the first part the author builds a theoretical model of the international mechanism of the world economy; and this is followed, in the second half of the book, by a series of statistical studies of the interwar economies of twenty-five countries in their international setting.

In brief outline the model can be summarized in three relationships: (1) fluctuations in a country's exports bring about fluctuations in its domestic activity; (2) fluctuations in national income influence the level of imports;

and (3) the volume of exports of each country is assumed to be determined by the level of world exports which, by definition, is equal to world imports. Taken together these relationships define, when aggregated, a closed system for the world economy. Two approaches are now possible. The analysis can either concentrate on the prime movers of the system, or else on the mechanism itself, *i.e.*, on the systematic part of the system. Polak has followed the latter procedure since he deals with autonomous factors as shocks and is primarily interested in how the system transmits these shocks and at what level it settles down if at all.

As far as the shocks are concerned he is almost exclusively interested in two types: autonomous fluctuations in investment and changes in relative prices, both on the export and on the import side. The importance of the former type is obvious; suffice it to say that with respect to fluctuations in world trade the key role is played by a few major industrial nations. Polak's treatment of the price factors is somewhat surprising and not completely convincing. In the first place he treats price changes as something given from the outside and not as a function of other variables in the system, say, of the levels of effective demand or output. Secondly, he argues that while changes in relative prices may lead to a reallocation of world trade, they are of much less significance for total world trade. But is that necessarily so? Take the case of the postwar imbalance in trade between the United States and the rest of the world. Was not one of the major arguments for depreciations and against discriminatory measures that the former would balance world trade at a higher level than the latter? Thirdly, even in the case of individual countries Polak plays down the importance of relative prices. If he argues that statistical evidence is on his side, there is reason to point out that no account is taken in the book of Orcutt's penetrating criticism of statistical methods similar to those used in the present volume.

When we turn to the three basic relationships listed above, the first one relating income to exports is the conventional multiplier analysis. It may be mentioned, however, that both on theoretical and on empirical grounds Polak decides against introducing time lags in his models. The ultimate value of the multiplier is independent of the existence or the magnitude of lags, and he also finds in the statistics little evidence of such lags between exports and income. Polak then introduces a concept which he calls the international reflection ratio, which represents a combination of the export multiplier and the marginal propensity to import. It indicates "the intensity with which the country under consideration reflects back into the world impulses it receives from the rest of the world." While the notion underlying the reflection ratio is not a new one but can be found, at least implicitly, in a great many other models, Polak's explicit treatment has a good deal of merit. The numerical value of the ratio measures the role played by individual countries in the propagation mechanism and its contribution to the stability (or instability) of the international system. In the statistical section of the study it is shown that the great majority of the countries analyzed are stable in the sense that the reflection ratio is below unity or, in other words, that the world system

is stable. This finding is described as one of the main results of the study.

In the last of the basic relationships, which explains exports of the individual country, Polak departs from a common procedure. Instead of explaining each country's exports as a function of world income, he correlates them with world exports. Quite apart from the question of the goodness of the fits, he argues that the use of world income is unsatisfactory for two reasons. It fails to make allowance for national differences in marginal propensities to import and, secondly, when the level of import controls changes, world exports is a better explanatory variable than world income. As Polak admits, his own approach is not completely general either, since he uses one total propensity to import for each country without allowing for different degrees of economic or political affinity.

In the statistical section the technique used is to fit linear equations by the least-squares method. The author refers to the critique of this method developed by the Cowles Commission, but believes, nonetheless, that it can be used in his models since he deals with simultaneous equations of the sequence-analysis type (no feed-back). But apart from this methodological question there is an additional reason why an appraisal of the statistical section is difficult to undertake. While all sources are indicated, no statistical raw material is presented in the volume itself. Moreover, the author mentions that a considerable amount of "doctoring" of figures and theory was made in order to yield a higher degree of conformity. However, since the exact nature of these adjustments is not described, the confidence of the reader in the findings must in the final analysis be based upon confidence in the "doctor." Finally there is, of course, the question of the applicability of the findings from the interwar years to the present period, a problem which is not discussed in the book.

Let me in conclusion mention that the present volume, while compact, is fairly easy to read. In contrast with some other many-country models, Polak only uses elementary mathematics (no matrix algebra). Together with the recent volume by Neisser and Modigliani, which covers approximately the same ground, it represents a valuable addition to the growing list of empirical studies of the world economic system.

SVEND LAURSEN

Brandeis University

Aid, Trade and the Tariff. By HOWARD S. PIQUET. (New York: Thomas Y. Crowell Co. 1953. Pp. vi, 358. $3.75.)

This book presents the results of an attempt to estimate the increase in U. S. imports which would be induced, under specified conditions, by the complete elimination of U. S. import duties and import quotas (together with the corresponding domestic support programs such as those for sugar, wool, butter). This audacious undertaking, written largely in 1951-52 and published in 1953, and being thus exposed to a considerable volume of critical hindsight, cannot well be denied a correspondingly large measure of charity from any reviewer who may himself not be unbruised by the experience of see-

ing quantitative trade estimates go awfully wrong. Any attempt to quantify what would otherwise be but vague estimates is clearly to be welcomed.

Nevertheless, the methods and assumptions of Professor Piquet's most industrious statistical investigations render it rather difficult to discover the real merit of this book. Apparently despairing of the feasibility of a purely econometric approach to his baffling problem, and at the same time attempting to gauge the detailed impact of tariff and quota abolition on the import-competing domestic industries affected, Professor Piquet took on the enormous tasks of preparing estimates of increases in import values separately for each item in the U. S. tariff list that showed an import value (c.i.f.) of $5 million or more (covering some 80 per cent of 1951 dutiable imports), on the basis of information, apparently largely qualitative, gathered from commodity experts in U. S. government agencies and elsewhere. While many will share his interest in the domestic effects of tariff and quota suspension, I am afraid that the assumptions from which his estimates start are highly damaging to his results. In addition, the published detailed bases for the (largely qualitative) judgment he exercised in arriving at his commodity estimates—as set out in the "Commodity Digests" (Ch. 10, pp. 79-358)—still leave much of the mechanics of estimation obscure.

The key assumptions (Ch. 3, pp. 11-20) are that, for as long as necessary for the effects of tariff and quota suspension to work themselves out, internal demand, domestic and import prices, area of origin distribution of imports, remain as they were in 1951, though not only the 1951 tariff rates and quotas but also the domestic price support and other control programs are assumed to disappear.[1] In addition, no attention is paid to the availability of exportable supplies abroad or to supply effects of these radical assumptions, and estimates for the imports of commodities on which duties were prohibitive in 1951, and for substitution effects as between imports resulting from universal tariff suspension had to be largely abandoned.

Some of these omissions are unavoidable in an exercise such as Piquet's. But 1951—the year in which the immediate post-Korean boom effects took hold on U. S. imports—was as abnormal a year as can be found after the second world war. Therefore, to pile what turn out to be generous estimates of quantity responses to the tariff suspension on the value and price levels of imports in that year cannot but lead to phenomenal results. It is true that the effect on Piquet's value estimates of the altogether abnormal 1951 prices can be disregarded—any monetary scale factor is as good as another—but it really makes little sense to compare the absolute results with the "dollar gap" however defined (*e.g.*, Ch. 4, pp. 21-36) in order to measure the extent to which "trade" might replace "aid."[2]

[1] It would take more restraint than can be expected from a reviewer not to quote the prize understatement of the book (p 20): "Some of these assumptions might not appear to be altogether realistic."

[2] Even Piquet's maximum estimate for the total import increase falls short of the 1951 "dollar gap" as measured by him ($4.6 billion). An elimination of government military aid and military imports from the balance of payments would reduce the statistical "gap" by at least $0.6 billion.

Knowing only partly how exactly they have been arrived at, one can thus only wonder at some of Piquet's detailed results. The total estimated import increase is given as $1.2 to 2.6 billion[3] or 11 to 25 per cent of 1951 total, and 25 to 55 per cent of 1951 dutiable, imports. Total import prices have since fallen by only about 10 per cent, and on this account alone, the overestimate would not seem to be serious. But Piquet's estimates are heavily affected by comparatively few raw materials. Unit values of all crude material imports fell by 30 per cent between 1951 and 1953, and those of the dutiable raw materials which figure prominently in Piquet's estimates fell by considerably more. Almost 45 per cent of the estimated total increase in imports following suspension of duties and quotas are attributed to three commodities, apparel wool, sugar and butter (p. 25). The absolute values of these three increases (doubling wool and sugar imports and increasing butter imports sixfold) are such as to yield total imports of apparel wool, sugar and butter of no less than $815 to 1.090 million, $580 to 775 million and $85 to 250 million, respectively. These figures, little short of millennial for the major supplying countries, lead (exports remaining constant) to trade surpluses of Australia, Cuba and Denmark—all countries typically in trade deficit with the United States—of the remarkable magnitudes of $300 to 450 million, $50 to 220 million and $60 to 65 million per annum, respectively. Wool prices have, since 1951, fallen to less than one-half their level then and the price of sugar shipped to the United States has been maintained at about the same figure only by the domestic support measures which Piquet assumes to disappear (the Cuban "world" price is down by more than 40 per cent). It is true that Piquet assumes a 50 to 100 per cent increase in U. S. imports of these commodities and that what happens to prices on that condition is anybody's guess—but that does not make his estimates more realistic.

At the same time, however, the 1951 distribution of imports by country of origin was quite abnormal: wool imports from sterling-area sources were abnormally high, from Latin America abnormally low, and butter shipments from Denmark were unusually large, coming in, as Piquet himself notes (p. 210), to relieve a temporary "hardship" of that country. On the other hand, his estimates for the increase in imports from major industrial countries are probably too low. At any rate, total actual imports from the United Kingdom, Germany, Italy and Japan in 1953 exceeded the figures estimated by him (Tables 1 and 10, pp. 32 and 77) on condition of tariff and quota suspension.[4] In other words, too much reliance on the 1951 record of imports from raw-material suppliers as a whole and from certain individual countries, and too little attention given to the recuperative forces operative in Western Europe, have warped Piquet's results. The former miscalculation is difficult to extenuate, while in regard to the latter he finds himself in a goodly company of scholars.

[3] The book presents minimum and maximum estimates throughout, the latter being generally twice the former. No clear reason is given for the size of the spread between the two.

[4] The cases of France and Belgium-Luxembourg, whose shipments were abnormally large in 1951 are exceptions, and so is that of Denmark

There is certainly no reason on general grounds to understate the importance for the rest of the world of reductions in the U. S. tariff and quota system, but more harm than good may come from overestimates. Nevertheless, it is a distinct merit of Piquet's exercise to have braved inevitable difficulties and to have attempted to reduce vague estimates to numerical magnitudes; unfortunately, however, his undertaking is needlessly defective. Considering the abnormal distribution of U. S. imports by countries of origin in 1951, estimates which simply apply the 1951 proportions to the future must be suspect, and this fact robs Piquet's computations for the relief to individual countries from the "dollar gap" (Ch. 4 and 9) of much of their value.

It is of some interest to observe, however, that even the estimates of this book for the impact of the import increases on that area of domestic industry which is defined as the "area of maximum competition" (p. 42)—*i.e.*, those industries in which tariff and quota suspension would lead to imports equal to from 10 to 90 per cent of domestic consumption—is quite small. Manufactured imports are estimated to form no more than 1.6 per cent of manufacturing value added, 2.6 to 3.1 per cent of the value of mineral production and 7.5 to 9.7 per cent of cash farm income (p. 46). In several individual industries—and, even more, in several geographical areas—the displacement effects may be serious.

The "Commodity Digests" (Ch. 10) which take up by far the largest part of the book, contain a good deal of useful information (though most of it is available in the Summaries of Tariff Information published by the Tariff Commission), especially on the relation between (1951) imports and domestic production. But the crucial points—namely the precise basis for the estimates of import increases—is, strangely enough, least well covered.

Cases and Problems in Marketing Research. By DONALD F. BLANKERTZ, ROBERT FERBER and HUGH G. WALES. (New York: Ronald Press. 1954. Pp. viii, 339. $5.00.)

Case books are becoming an increasingly important part of marketing literature, and *Cases and Problems in Marketing Research* is a welcome addition to the list. It is also the first major contribution of this type to the field of marketing research, an area in which close contact with management problems is particularly helpful. As the authors state in the preface, "It is increasingly recognized that principles and methodology descriptively studied fail to prepare the student sufficiently to deal effectively with marketing research problems in the field."

The book was written to be used in three different ways: (1) In conjunction with a basic textbook in an introductory course in marketing research; (2) As the text in a course in applied marketing research which follows an intro-

ductory course; (3) As the text in an introductory course taught by the case method. This is a difficult assignment, but the authors have accomplished their purpose. As it stands, the book may be used in the first two ways, and with the addition of supplementary material it may meet the third need also.

The material is organized along functional lines and is grouped under nine headings: Formulating the Problem, Preliminary Investigations, Planning, Sampling, Collection of Data, Editing and Tabulation, Analysis and Interpretation of Data, Presentation and Follow-Up, Organization for Research.

These subject areas carry the student through the several steps of marketing research in a logical, orderly procedure. It is the plan of the book to present in each section a short, concise treatment of the high lights of the subject. This gives in summary form the basic principles and procedures needed to handle the cases and serves as an introduction to them. There is also a brief statement covering each of the cases which helps to orient the reader in their use.

The book contains 56 cases, and each of the nine functional divisions has a selection of cases which deal with typical problems in that phase of research. The cases vary in length and complexity and cover a wide scope with respect to types of research situations and fields of business. The result is a very interesting group of problems which will stimulate the thinking of students and give them a sense of the many different applications of marketing research techniques.

In quality, the cases vary from fair to excellent, as is typical of case books, but the general level is high. The presentation of the cases follows, fairly consistently, a logical organizational pattern which includes the background of the case, a statement of the problem, a brief recital of the data available, and the action needed. The latter is stated in the form of a few questions which will help the student analyze the case. Some of the cases also give suggestions for class assignments. The cases are reasonably complete although they are not as elaborate as some of the Harvard case materials in marketing.

One feature of the book, which will enhance its usefulness in the classroom, is the annotated bibliography which is found at the end of each introductory section.

This book merits the careful attention of teachers of marketing research.

Industrial Organization; Public Regulation of Business

Basing Point Pricing and Regional Development. By George W. Stocking (Chapel Hill: University of North Carolina Press. 1954. Pp. vii, 274. $6.50.)

This recent volume by Professor Stocking presents an objective, authoritative, and challenging analysis of basing-point pricing and the public welfare.

Stocking finds that "basing point pricing developed in iron and steel as a means of stabilizing the industry," and that the "combination movement in

iron and steel at the turn of the century greatly simplified the Steel Corporation's role as the 'great stabilizer.'" More specifically, he states that basing-point pricing, as a general practice, was "adopted concertedly by business rivals anxious to escape the rigors and uncertainties of unrestricted competition"; leaders in the steel industry turned to basing-point pricing because of their experience and belief that "unrestrained competition," particularly during periods of slack demand, gives rise to results which are "ruinous," "tyrannical," and "destructive." In their view, steel producers are under strong compulsion to "cut prices"—usually in a discriminatory way—when supply exceeds demand because of high fixed costs and a technical need to keep furnaces in operation. Although lower prices for steel will increase the customers of a *particular* seller, it is believed that they will not increase the *total* demand for steel. The drive to make sales, therefore, in their thinking, forces prices in some areas or to some buyers to ruinous levels.

Basing-point pricing, Stocking finds, has served the interests of influential industry members in restraining price competition and in providing greater profits. But what have been the consequences and effects of the practice on the economy of the South? A thorough analysis leads the author to conclude that: "Basing point pricing in steel has contributed to the South's poverty by curbing the expansion and utilization of its steel-making facilities and by retarding the growth of steel-consuming industries." Birmingham was a "low cost producing area," but under Pittsburgh-Plus consumers were denied the advantages of their location. After 1938, with the introduction of multiple basing points equalized with Pittsburgh, moreover, the South continued to be handicapped, because the Birmingham mills could not use their lower costs to make competitive price reductions and expand sales in the southern areas. Other deleterious effects of basing-point pricing include the maintenance of prices at high and rigid levels, the practice of granting discriminatory lower prices to large customers, the inclusion of fictitious freight charges for use in subsidizing sales in distant markets, the cross-hauling of steel products, and the growth of cost-raising methods of doing business.

Stocking's appraisal of basing-point pricing is most impressive, disturbing, and challenging. It deserves to be widely read by businessmen, economists, congressmen, government officials, and lawyers. Its significance applies, moreover, not only to the South, but also to the West, and to the nation as a whole.

Chapter 8, The Law on Basing Point Pricing, provides an up-to-the-minute summary of (1) the courageous and intelligent attack on basing-point pricing by the Federal Trade Commission; (2) the gradual weakening of the Commission's attitude toward systematic discrimination; and (3) the final acceptance by the Commission of the steel industry's demand for discriminatory delivered pricing and freight absorption "when innocently and independently pursued, *regularly or otherwise,* with the result of promoting competition" (Iron and Steel Order, 1951).

Stocking's analysis of basing-point pricing, I believe, will find a wide area of agreement among economists. His proposals on policy (action), however,

are likely to encounter some differences of opinion. Few will disagree that systematic basing-point pricing through collusive action ("what we have had") should be forbidden. But what of the alternative of permitting freight absorption, freight equalization, and freight allowance, "independently" pursued? Stocking appears to look with favor upon this alternative, believing that it is "a sound business practice" which "intensifies business rivalry." Here, I suggest, there is a serious dilemma. If two or more geographically separate mills quote their own f.o.b. mill prices and then regularly discriminate (by absorbing freight) to meet delivered prices in each other's "back yard," are they not getting the same result as the concerted use of a multiple-basing point system (Count II in the *Cement* case)? Is not the practice one of conscious parallel action (Count II in the *Conduit* case)? Is not the buyer again faced with the stone wall of price identity? Similarly, if two or more geographically separate firms regularly absorb freight in freight-allowed or zone pricing, how can the practice withstand the inference of conspiracy (*Crepe Paper, Malt,* and *Milk Can* cases)? Moreover, if freight is absorbed not to match but to undercut a distant rival's delivered price, is not the practice one of cutthroat competition, whereby smaller, though efficient firms, can be brought to terms by large, multiplant concerns able to make up temporary losses in other areas where no competitors survive?

"Unrestrained competition" in given situations may undoubtedly result in ruinous competition. Geographic separation of producers, high fixed costs, and other factors give sellers degrees of local monopoly power which they can, and do, use in discriminatory pricing. This can be ruinous. Such conditions, it may be urged, provide the reason for making geographic discrimination prima facie illegal. Basically, it appears, we must choose between (1) the acceptance of regular and systematic freight absorption (basing-point pricing) or (2) the condemnation of its cooperative use by two or more sellers. As Mr. Charles L. Hogan, President, Lone Star Cement Company, testified in the *Cement* hearings, the only workable alternative to f.o.b. mill pricing is "f.o.b. *destination* pricing," *i.e.*, some form of basing-point or zone pricing. The basic problem which must be grasped is the significance of the practice of price discrimination. Is price discrimination a competitive or a monopolistic practice?

VERNON A. MUND

University of Washington

Private Enterprise and Public Policy. By MELVIN ANSHEN and FRANCIS D. WORMUTH. (New York: Macmillan. 1954. Pp. xiv, 742. $6.75.)

In our society government and private enterprise impinge upon one another in many ways, a number of which are pointed out and described in this new textbook. With the sugar industry and railroads as illustrations, the opening chapter usefully indicates the effects of pressure groups on public policy. Constitutional and administrative principles are outlined in the next two chapters. Part II, "Techniques of Governmental Action" (mainly federal) has eight chapters: antitrust and other trade regulation (two chapters); "governmental preconditions to business action" (incorporation, licensing,

etc.); control of rates, prices, and wages; "governmental benefits" (discussed below); regulatory taxation; governmental operations (fiscal and monetary, government ownership, and yardstick competition); and business self-government. Chapters in Part III, "Public Policy in Special Areas," cover: the power industry; transportation; communications; finance (banking, insurance, investment banking, public finance, and international finance); agriculture; labor; the war economy; and economic depression. Part IV, "Administrative Problems," begins with two chapters that present a half-dozen short case studies and ends with one on "planning."

One must judge a textbook with the subject matter and approach of a particular course in mind. There are many varieties of junior or senior classes in "government and business" for which this book is intended. For example, although the subject requires a blending of political science and economics, one or the other may be emphasized. This review is concerned only with the usefulness of the book for courses stressing economics and for which a course in principles of economics would be prerequisite. For such courses the book is disappointing in its organization and in the level of its analysis.

Surely there is something wrong with a principle of organization that groups into one chapter (because all are "governmental benefits") patents, copyrights, crop insurance, the Federal Housing Administration, the Reconstruction Finance Corporation, deposit insurance, the Export-Import Bank, the Maritime Administration, the War Damage Corporation, agricultural price supports, public lands, and postal subsidies. All these—and more, for I have omitted a number of topics—take 32 pages; a two-page "evaluation" follows! No chapter is more heterogeneous, but as the summary above indicates, others are similar. Sometimes, too, essentially related material is arbitrarily separated. Will students reading the chapter on the power industry recall *Smyth v. Ames* and the *Hope* case from the discussion of "Control of Rates, Prices, and Wages" 150 pages earlier?

The level of presentation only occasionally rises above that of the better elementary economics books. The sections on monetary and fiscal policy nearly fall below that mark. In particular, the authors do not take much advantage of their opportunity to use the tools of analysis that students have acquired in their introductory economics course. For example, after a very sketchy set of market-structure definitions, the chapters on antitrust turn to a series of laws and cases emphasizing legal rather than economic tests. The problem of reconciling law and economics never comes through. After an extremely short discussion, antitrust control of oligopoly is dismissed as impossible. Near the end of the book there is a section on "practical problems in antitrust operations," but the ones discussed are size of staff, appropriations, and the like, rather than the fundamental difficulties of defining intelligent economic policy. Because the authors do not work from an explicit analytical framework, the sections that close many of the chapters are mere summaries, not "evaluations" as their headings promise.

The authors' encyclopedic coverage of problems, statutes, and government agencies will give students a feeling for the manifold interrelations of private

and public activity. But perhaps a brief aerial survey would be a more economical way to accomplish that useful task, so that the major space could be allocated to a detailed treatment of a smaller number of subjects. Also, it would be better to give monetary and fiscal policy, labor, and perhaps other subject areas, as courses in their own right, rather than as short stopovers in an omnibus course.

What will students carry away with them from a course in "government and business"? Unless the subject can be narrowed, and the analysis deepened by building it around an analytical framework, they will retain at the most—and only if their memories are exceptional—a list of statutes, cases, and agencies. What they need is a real grasp of the economic (and political) issues in forming public policy in relation to private enterprise. This textbook will not lead to this result; and I am all the more regretful of the necessity of so reporting because the quality of the discussion in certain places, the excellence of the "selected references," the authors' familiarity with day-to-day governmental operations, and their balanced and good-tempered attitude toward public policy all suggest that they might have reached that goal. I am sure that my most critical remarks apply less to them than to the market they have tried to serve.

Public Utilities; Transportation; Communications

The Pacific Coast Maritime Shipping Industry, 1930-1948. Vol. II, *An Analysis of Performance.* By WYTZE GORTER and GEORGE H. HILDEBRAND. (Berkeley and Los Angeles: University of California Press. 1954. Pp. xix, 371. $5.00.)

The second volume of this study of the Pacific Coast shipping industry presents the authors' analysis of the underlying causes of the dismal picture of secularly declining demand, pronounced short-run instability, and stagnant employment opportunities painted in Volume I.

The first two chapters include a concise summary of the commodities carried in the four "trades" which comprise the industry and of the geographic pattern of its foreign commerce. The remainder of the book is devoted to the formulation and quasi-empirical testing of a series of hypotheses as to proximate causes for the industry's poor performance in the period 1930-1948.

Some of these are necessarily routine in nature and are so treated. Thus the conclusions that commercial policies of the 'thirties operated to reduce the demand for maritime services and the reciprocal trade agreements to increase them are neither debatable nor—unfortunately—measurable from the data available to the authors. The same might be said of the influence of general economic fluctuations, war, and work stoppages on short-run instability in the demand for shipping and longshore services. In none of these instances does the empirical material add much to conclusions quite evident in advance.

Subsequent chapters are more interesting and provocative. The thesis that

the extraordinarily rapid growth of the Pacific Coast regional economy not only failed to stimulate the maritime industry, but actually worked to its detriment is persuasively developed, despite the acknowledged necessity of reasoning from circumstantial evidence.

The authors properly stress the fact that these factors, together with the steady worsening of the competitive position of water carriers vis-à-vis foreign shippers and rail and motor transport, created an environment in which no internal industry policies could have achieved more than a more orderly retreat. Nevertheless, interest in this study will almost certainly center on the chapters dealing with the almost unbelievably bitter and frustrating relationships among employers and the maritime unions from 1934 to the present.

As careful and scholarly observers, the authors are at pains to present fully the claims and counterclaims, the overt and the hidden issues, the honest and the dishonest techniques of both sides. Anyone familiar with the industry will be aware of the fact that to do this intelligibly is a task of no mean proportions, and in this instance the presentation is admirably concise. Yet the battles were so vicious, and their consequences so detrimental to all in the industry, that one almost inevitably takes sides; and this is clearly evident in the present volume.

The authors find—properly, I think—that the failure to develop a mutual recognition of interlocking interests reflects the absence of the intent to bargain in good faith. And though they make no attempt to gild the employer group, the failure to reach a satisfactory *modus vivendi* after the 1937 settlement is attributed largely to the intransigence of the International Longshoremen's and Warehousemen's Union; more specifically, to the policies of Harry Bridges; and, still more specifically, to the Communist ideology which they feel accounts for those policies.

It may well be that these conclusions are close enough to the truth to constitute an important part of the explanation of the industry's sorry record of work stoppages and the persistent tendency to price itself out of most of its markets. But in this volume they are emphasized to the point of glossing over the sometimes equally unreasoning truculence of the employers' bargaining units, and the latent hope and desire that unionism could be shackled if not destroyed which cropped out again after passage of the Taft-Hartley Act. Equally questionable is the constant reiteration of the "irresponsibility" of the ILWU leadership, against which the actions of Lundeberg and the Sailors Union of the Pacific show up in the book as "tough" but "mature" and thus more consistent with the end of mutual recognition of interests.

It should be reiterated that the authors have outlined the basic facts concerning the development and techniques of collective bargaining in the industry without bias and in terse, effective style. The conclusions they draw are not forced on the reader, and others may well be drawn from their own presentation.

As in all careful analyses of industry structure and performance, this study derives much of its value from the compilation, evaluation, and organization

of source materials not readily available elsewhere. Except for some repetition dictated by the somewhat arbitrary division into two volumes, the books make unusually easy reading, largely because the authors have a pleasant willingness to use English where technical jargon would do.

JAMES A. CRUTCHFIELD

University of Washington

Economics of Canadian Transportation. By A. W. CURRIE. (Toronto: University of Toronto Press. 1954. Pp. vii, 727. $10.00.)

The present volume is the first general treatise on Canadian transportation to appear since the late Professor Jackman's *Economics of Transportation,* published in 1935. It is similar in scope and organization to the latter and also to some of the standard American texts on transportation. The primary emphasis is on rail transportation but there are individual chapters on highway freight transportation, highway passenger transportation, inland water transportation, ocean transportation and air transportation. The author states in the preface that he has attempted to meet the needs of various classes of readers, particularly "the smaller shippers who from time to time have to appear before one or other of the regulatory authorities" (p. v). He does not mention the possible use of the volume as a text in college and university courses in transportation.

The discussion of rail transportation is concerned primarily with the rate level and rate structure. Three chapters, totaling 115 pages, are devoted to the evolution of the rate level. These chapters will be valuable to specialists, but some may feel that they are too detailed for a general treatise. The chapter dealing with the theory of railway rates is adequate but, in the reviewer's opinion, open to criticism in one respect. After referring to the relation of decreasing cost to railway rate-making he says, "The other principle or economic 'law' underlying the theory of freight rates on individual commodities is that of joint cost" (p. 159). Later in the chapter, however, when he summarizes the controversy between Taussig and Pigou as to whether it is joint cost or monopoly which explains discrimination in railway rates, it may be inferred that he agrees with Pigou, for he says that "On the whole railway history has substantiated Pigou's point of view" (p. 170). If this interpretation is correct it would seem that the author should have given primary emphasis to the role of monopoly in explaining railway rate discrimination, with only incidental reference to joint cost in view of its very limited applicability in this field.

The volume portrays very well the significant similarities and differences between American and Canadian transportation policies. Thus the equalization of railway class rates in the United States, except for Mountain-Pacific territory, has been paralleled by equalization in Canada, except on the White Pass and Yukon Route and in the Maritime Provinces, effective March 1, 1955. On the other hand, in contrast to the situation in the United States, the regulation of highway transportation has been left entirely to the provinces, apparently in part for political and constitutional reasons and in

part because interprovincial and international highway traffic amounts to no more than 3 to 5 per cent of the total. The scope of regulation is similar to that in the United States in the case of bus transportation but is less comprehensive in the case of trucking. Thus all the provinces regulate bus fares and all but Newfoundland require bus operators to secure certificates of convenience and necessity. All except four of the provinces require certificates for common-carrier truck operation, but only three effectively control common-carrier trucking rates. Contract carriers are subject only to safety regulation.

Canadian policy with respect to air transportation is of interest in view of the controversy in this country as to whether airlines should be regulated by the same agency which regulates other forms of transportation or by a separate agency, and whether surface carriers should be permitted to control airlines. Beginning in 1938 the regulation of air transportation in Canada was entrusted to the Board of Transport Commissioners which at that time also had jurisdiction over railways and certain inland water carriers, as well as express, telephone and telegraph companies. In 1944 dissatisfaction with the Board's regulation of air transportation led to the transfer of its regulatory authority in this field to a newly created Air Transport Board. At the same time surface carriers were ordered to divest themselves of control over airlines, but the order was not made effective immediately and in 1946 was modified so as not to apply to the Canadian Pacific and Canadian National railways.

Finally, it may be noted that the chapter on ocean shipping reveals that there is much similarity in the problems of the Canadian and American merchant marines and in the policies pursued with respect thereto.

In the reviewer's opinion the author might well have included a chapter on railway accounting and accounting regulation and one on the effect of freight rates on the location of industry. There are no maps, charts or statistical tables and the usefulness of the volume would have been materially enhanced, especially for American readers, if at least a few such aids had been included. There are extensive footnotes but their usefulness is greatly reduced by being placed together at the end of the volume. Finally, it is unfortunate that the publisher should have thought it necessary to put a $10 price on the book. However, these criticisms do not alter the fact that both American and Canadian students of transportation are heavily indebted to Currie for preparing this thorough, well-written and much needed study.

Land Economics; Agricultural Economics; Economic Geography

Methods of Crop Forecasting. FRED H. SANDERSON. (Cambridge: Harvard University Press. 1954. Pp. xiv, 259. $5.00.)

This book reviews methods currently in use for forecasting crop production and explores a number of techniques for refining existing procedures. In the

words of the author one of the objectives of the book was to "present in summary form the contents of a large and widely scattered literature." Certainly Mr. Sanderson has done this part of his work well. The book summarizes studies touching on important phases of crop forecasting both from the United States and other countries. The study is especially timely in that it comes during a period of increased activity on the part of the U. S. Crop Reporting Service to improve the accuracy of its estimates.

Part I examines the statistical tools that are useful in crop estimation. The author presents no statistical techniques not reported elsewhere but he does perform the highly useful function of bringing together in one place the major statistical developments of value in crop forecasting.

Part II moves to a study of methods of estimating and forecasting acreage. Part III deals with problems of forecasting the yield of crops in advance of the harvest. In this section, Sanderson devotes considerable attention to errors arising out of inaccurate observation or bias on the part of the crop reporter as distinguished from sampling error and bias associated with the selectivity of the sample.

Part IV explores possibilities for refining estimates by basing crop forecasts on the observation of ecological and weather variables. While such a system would sidestep many of the problems involved in predicting yields through observation of the condition of growing crops, Sanderson emphasizes that efforts in this direction are handicapped by a lack of adequate meteorological data and well-defined hypotheses concerning the causation of yields.

The author points out several areas in which the forecasting procedures employed by the Crop Reporting Service have failed to keep pace with the development of improved techniques. However, he is somewhat more tolerant of the shortcomings of the estimating procedures now in use than many other critics and displays an acute awareness of the limitations imposed by budgetary restrictions and the need for economizing in crop forecasting activities. He explores several sampling devices which, while involving a loss in "statistical efficiency," increase the economic efficiency of the estimating procedure.

The book is well written and should be comprehensible to anyone with an understanding of the concepts presented in the basic courses on statistical methods. It should prove highly useful to those interested in bringing themselves up-to-date on the present status of crop estimating procedures with a minimum of effort.

RAYMOND R. BENEKE

Iowa State College

Real Estate Finance. By HENRY E. HOAGLAND. (Homewood, Illinois: Richard D. Irwin, Inc. 1954. Pp. ix, 515. $6.00.)

This book contains information on almost all aspects of real estate financing; however, it is basically concerned with presenting home financing procedures rather than a thoroughly definitive discussion of the principles and problems of real estate financing. The twenty-seven chapters contain three principal categories of information: (1) descriptions of real estate financing

instruments, (2) a review of the characteristics of the principal sources of real estate mortgage funds and the procedures used in disbursing these funds, and (3) a general statement of government home financing programs.

The volume is written in a narrative descriptive style and provides general indoctrination in the home financing procedures in which the author believes. Professor Hoagland's many years of teaching, business and governmental experience in real estate provide the background from which he develops in broad outlines general real estate financing principles and procedures.

The book has been written for students as well as practitioners and should be useful to the student who has completed one semester of real estate principles; to the practitioner with only limited experience in home mortgage lending; as a supplementary text in an introductory course in real estate stressing real estate financing; and as a general review of basic home financing principles and procedures for the advanced student and the experienced practitioner.

The author's approach to real estate financing is broader than those of other authors on real estate financing who typically stress the lenders' views on mortgage financing. He discusses real estate financing from the viewpoint of (1) the lender, as in Chapter 20 "Mortgage Loan Servicing," (2) the borrower, as in Chapter 1 "Introduction," and (3) the practitioner, as in Chapter 18 "Appraisal for Financing Purposes." Although home financing is stressed, he also includes chapters on financing farms, subdivision and development financing, and federal housing programs.

The book would have been strengthened by inclusion of more complete discussions of such aspects of home financing as new-custom-built home construction financing, the steps in the home financing process, mortgage loan appraisal for single-family homes, regional differences in mortgage financing, and the impact of neighborhoods and districts on lending terms. The analyses of institutional lenders, government impact, and federal housing programs would have been more meaningful if they had been preceded by brief summaries of money markets and the flow of funds into mortgage markets. Advanced students of real estate and experienced practitioners will want to supplement the discussions of institutional lenders, lending instruments, and governmental housing programs with a review of the National Bureau studies in real estate finance, Housing and Home Finance Agency real estate research reports, and other recent real estate research publications referred to only infrequently in the book.

The author does not attempt to speculate on such vital topics as the reasons for the growth of savings and loan associations in the postwar period, the implications of increasing federal support for single-family home financing, the basis for the trends to long-term, high loan-to-value, low-interest-rate home mortgage loans. Definitive evaluations of these and similar matters by a scholar of Hoagland's stature would have increased the usefulness of the book for the mature student and the experienced lenders.

The book is welcome because it brings together the newest as well as the most generally accepted principles and procedures in real estate financing.

Hoagland has performed a service in synthesizing the many varied aspects of real estate financing into simply stated principles and procedures. Other scholars should be challenged to study these principles and procedures and test them in the light of the continuing stream of research materials now being published on real estate finance.

University of California, Los Angeles

Labor

Manpower in the United States: Problems and Policies. By WILLIAM HABER, FREDERICK H. HARBISON, LAWRENCE R. KLEIN, and GLADYS L. PALMER, editors. (New York: Harper & Bros. 1954. Pp. xi, 225. $3.00.)

In the opening essay of this collection, called "Work in the Life of an American," Daniel Bell emphasizes the profound influence of scientific management, with its "division of labor" and "fragmentation of work" upon the life of the American laborer. He might have gone a step further. The book itself is an example of the "task system" in scholarly output. It is another sample of that increasingly common academic performance, the collective treatise: 225 pages long, four editors, sixteen essays, and twenty authors.

Manpower in the United States is introduced by the editors as a study in the "specialized branch of economics . . . in which the concept 'manpower' specifically denotes labor market dynamics and labor force characteristics and attributes" (p. ix). If this definition leaves the reader with something less than a crystal clear understanding of the job territory of the manpower economist, he may read on to discover that "from studies of these matters policy is both evaluated and created. . ." and that, in the editors' collective opinion, "the objectives of public policy today" should be: (1) to maintain a high-level employment economy. . . . (2) to build and maintain a stable work force. . . . (3) to utilize the labor force efficiently through proper matching of jobs with people, effective management, and the appropriate education, training, and development of people, and thus to raise the productivity of labor and the general standard of living throughout the nation. (4) to provide reasonable security against . . . illness, unemployment, disability, and old age. (5) to preserve and enhance the freedom, dignity, and worth of the individual. . . . (6) to provide the proper . . . distribution of manpower between our armed forces and civilian work forces. . . ." (pp. ix-x).

Not quite all of the above matters are covered in the present volume. The book has three main parts: I. "Utilization and Motivation of Workers" (five essays), II. "Changing Dimensions of the Work Force" (seven essays), and III. "Manpower Mobilization" (four essays). It has also the unevenness of quality, the diversity of treatment, and the tendency toward repetition of many such collections. *E.g.*, it ranges in quality from a few brilliant and informative chapters by Bell (see above), Wolfbein ("The Geographic Distribution of Nonfarm Employment"), Bancroft ("Trends in the Labor Force"), and Ginzberg and Anderson ("The Shape of Military Manpower

Policy"), on down to several thoroughly pedestrian summaries of standard labor problems and Solomon Barkin's hard ride on his hobby of "Job Redesign: A Technique for an Era of Full Employment." (Barkin's thesis: criticism of hiring officers, who "look for the most productive person among, rather than the best job for, the applicants. . . . The convention is that people must be suited to the jobs rather than jobs to the people" [p. 40].)

The author list is imposing and the title list intriguing. The essays mentioned above are excellent and one or two others are almost as good. However, for this reviewer at least, the book as a whole simply did not come off. There was no sense of unity, no feeling of approach to "a problem," simply a collection of pieces, ranging from good to ordinary, on a variety of topics. Perhaps the fault is the reviewer's; perhaps the fault lies in the approach, the target being too big; or perhaps, just perhaps, this is carrying division of labor too far and we should recombine some of the jobs in manpower economics to bring back a sense of work significance to the laborers in that classification.

O. W. PHELPS

Claremont Men's College

The Impact of Strikes: Their Social and Economic Costs. By NEIL W. CHAMBERLAIN and JANE METZGER SCHILLING. (New York: Harper and Brothers. 1954. Pp. viii, 257. $4.00.)

Estimating the cost of strikes, as of other kinds of warfare, is a tantalizing problem. While it is easy enough for the partisan to command sympathy for the losses of those he favors, to make a dispassionate appraisal of net effects is a different matter. Many of the relevant statistics are unavailable; people are affected in varying degrees; and the proverbial truths that one man's meat is another man's poison and that it's an ill wind that blows nobody any good are only too applicable. "Because of these conflicting factors," wrote Florence Peterson of the U. S. Bureau of Labor Statistics in 1937, "an estimate of the cost of individual strikes or the cost of all strikes in a given period is misleading as well as inaccurate"; and more recently the Bureau has described the making of such estimates as an "impossible job." This has not deterred the authors of the present study—and will probably not deter others—from attempting it.

Professor Chamberlain has made a heroic effort to simplify his problems. After describing his method, which in conception is both ambitious and novel, he applies it to seventeen large strikes (11 coal, 3 rail, and 3 steel), mostly postwar. He enumerates the various "publics" presumed to be affected by the strikes; and he tries to measure, for each of these "publics," first, the importance to them of the particular good or service in question (its "cultural necessity" to consumers, "production necessity" to dependent producers, etc.); second, the extent to which on a particular day—usually at the peak of the strike—supplies could be maintained from stocks ("stock effect"); and third, the extent to which substitutes could be found ("substitutability"). Each of these effects is rated on a 10-point scale, and the readings are combined in

such a way as to give an "urgency rating" for the particular "public" considered. The various urgency ratings are then multiplied by the estimated sizes of the respective "publics," and a total strike rating is arrived at which can be compared with those for other strikes.

Unfortunately the very neatness of the method underlines the tenuity of the data on which the results are based. Certain of the figures used come from official reports; some are from newspapers; but many of the estimates—notably those relating to "cultural necessity," "market necessity," "substitutability" and the recoverability of strike losses—are the purest guesswork: "an allowance of 60 per cent is made for recoverability, . . . but an additional allowance of 90 per cent of strike losses is considered to have been offset by the close concern of strikers' families with the outcome of the dispute." The procedure is inevitably, if sometimes alarmingly, flexible: "if this procedure too grossly understates the effect, then additional categories may be added." The detailed discussion of the effects of particular strikes on particular "publics" is interesting as speculation, and the argument sometimes appears cogent enough (for example, the commonsense conclusion that household consumers are not necessarily the most important sufferers was certainly worth stressing); it is the insistence on dubious statistics that is disturbing. "The advantage of the rating device is that it forces the assessment, in relatively precise terms, of all the numerous variables which together determine the impact of a strike on the public." But "relatively precise" is a scarcely permissible euphemism, and "all" is certainly an exaggeration.

A wider purpose of the book is, according to the jacket, to "provide an important new basis for realistic legislation." Legislation is founded on rights; and the social philosophy of the authors is based on "rights of expectation" (expectation of buying what we need and selling our goods and services in order to be able to do so): "to the extent that a strike inconveniences us, then, it frustrates our rights of expectation, rights which are just as surely built into our culture as if they were matters of law." But what of the strikers' "rights of expectation"? Those who are "inconvenienced" by, say, the withholding of a wage increase which they consider overdue might fairly ask Chamberlain by what hedonistic calculus he would balance their rights against "ours." The striker is, indeed, the most stubborn factor in the situation, and the authors virtually ignore him in their very natural concern for his victims, the "public." "There is rather clear evidence that large sections of the public would welcome almost any substitute for the strike." What substitute? If an inconvenient strike can be averted only by granting an exorbitant demand, or outlawed only at the cost of producing chronic industrial apathy or unrest, the price may be greater than the benefit bought. In any serious strike situation, the action taken may profoundly affect the future course of relations within the industry; and in such a context the public's immediate reactions may be largely irrelevant. Thus even supposing that the sort of effects discussed in this book could be predicted accurately (which they certainly cannot), short-term economic expediency is not necessarily a very good guide to action. This is after all the core of the strike problem—a problem which.

after credit has been given to the present authors for their enterprise, remains beyond the reach of so narrow an economic analysis.

K. G. J. C. KNOWLES

Institute of Statistics, University of Oxford

Collective Bargaining in the Railroad Industry. By JACOB J. KAUFMAN. (New York: King's Crown Press. 1954. Pp. xi, 235. $3.75.)

This is a modest, useful book which will, no doubt, be a handy reference for its period. It does what it sets out to do, namely to give the background of the Railway Labor Act and to study its operations in detail from the amendments of 1934 to 1952. The author has been employed somewhere in the field of railway personnel administration and it seems to have been a labor of love for him to gather up the available references and to present a complete if condensed story.

Those who are not technicians operating in this field will, however, wish that Mr. Kaufman had raised his sights a little bit. Here is a record of the declining power of capital and the rising power of labor displayed with a clarity found nowhere else in America. By 1916 the Railway unions were able to make the Congress jump through hoops at command. It was a foretaste of the great and permanent change of 1933.

The economic literature is full of the efforts of monopolistic competitors to find their way through the maze of legislation and regulation set up to frustrate their efforts. The running trades have no such problem. They are a monopoly and make no bones of it. They freeze working conditions and prevent agreement with individual roads for the more intelligent application of labor in order to preserve what they think are their advantages.

From about 1920 the railways' share of the national income was declining. The numbers of their employees shrank both absolutely and relatively. Their differential advantage over workers in the manufacturing industries also shrank as the latter also organized.

The very high degree of organization of railway workers does not change the nature of the ultimate adjustment (except, possibly, by making the final position worse than it might otherwise have been), but it certainly does change the path by which it is reached.

It is a misfortune that Kaufman was not greatly interested in the forest; but he has given a good description of the trees he chose for his own.

JOHN L. MCDOUGALL

Queen's University

Modern Labor Economics; An Analysis of Labor-Management Relations. By PEARCE DAVIS and GERALD J. MATCHETT. (New York: Ronald Press. 1954. Pp. xviii, 659. $6.00.)

This is a worm's eye view: the student enrolled in the introductory course in labor economics looking at a proposed text. What standards, we may inquire, would this fellow expect the book to meet and how does this particular volume measure up?

He would insist, first, on comprehensiveness, on dealing with all the topics needed for a basic understanding of labor problems. The authors acquit themselves very well on this score.

Second, he would expect the volume to be systematic, to hang upon a logical framework. Here, again, Davis and Matchett score. Their structure makes sense and it is not hard to find the discussion of a particular topic.

Third, he would like to come away from the book with a set of insights that help him explain the world of labor. In several instances, for example, the description of the trade union, the discussion deals only with formal, surface phenomena. Although the information is quite accurate and the writing is not without a certain sophistication, there is little penetration.

Fourth, he would want his text to do too little rather than too much, to hit the key ideas and omit the factual tonnage, which can be found in supplemental readings. Here, too, the treatment is not satisfactory. The freight carried by the book is too heavy and the reader staggers under the load. Much of it, for example the discussion of types of economic enterprise, could be dispensed with.

Related to this is the fifth point, that the style should exhibit both lucidity and brevity. The volume opens smoothly; after a while, however, one notes a certain fatigue creeping into the writing and, as is common in collaborative enterprises, unevenness. As already noted, the book is too long.

Sixth, our student insists that the authors make up their minds about the case method. Either they compile a casebook or they write a text. It is disconcerting to find a random patchwork of illustrative material.

Finally, he expects that the suggestions for further reading will penetrate the subject matter more deeply He is disappointed to find bibliographies heavy with references to other text books while omitting standard monographs.

To sum up, in a room crowded with texts for the elementary labor course this one is likely to be jostled to the rear. It will do, but it will not inspire.

Employment of economic resources. (Wellington: Reserve Bank of New Zealand. 1954. Pp. 36. 3 *s.*, 6 *d.*)

Levnadskostnader och reallöner i de nordiska huvudstaderna (Cost of living and real wages in the capitals of the Northern countries). Nordisk Statistisk Skriftserie. (Stockholm: K. L. Beckmans Boktryckeri. 1954. Pp. 92.)

The purpose of the study has been to compare, as of April 1952, cost of living and real wages in the Scandinavian countries. Actually, the comparisons are made only for the capitals—Copenhagen, Helsingfors, Reykjavik, Oslo and Stockholm. Since this is the first time such a comparison has been undertaken, considerable attention has been devoted to theoretical problems and to questions of method. (An English summary is provided.)

Obtaining financial aid for a development plan—the Export-Import Bank of Washington loan to Afghanistan, Sept. 30, 1953. Prepared by the Senate Committee on Banking and Currency. (Washington: Supt. Docs. 1954. Pp. 55.)

Record of proceedings Third Asian regional conference, Toyko, September 1953. (Geneva: Internat. Lab. Office. 1954. Pp. vii, 211. $3.)

Business Fluctuations; Prices

COLM, G. *Entwicklungen in Konjunkturforschung und Konjunkturpolitik in den Vereinigten Staaten von Amerika.* Kieler Vortrage 6. (Kiel: Inst. für Weltwirtschaft, Univ. Kiel. 1954. Pp. 23.)

GRAYSON, H. *Economic planning under free enterprise.* (Washington: Public Affairs Press. 1954. Pp. x, 134. $2.)

The author points out that today, more than ever before, the state is concerned with national planning and control with particular regard to the general level of employment and income. Hence governments have become involved in forecasting. This book is concerned with the actual processes of analysis and forecasting employed in a number of different countries: the United States, Canada, Great Britain, Sweden, the OEEC countries.

Economic report of the investigation of coffee prices, July 30, 1954 Federal Trade Commission. (Washington: Supt Docs. 1954 Pp xlviii, 523. $2.)

"This is the first of a series of reports based on a two-year investigation of industrial relations policies and practices in 80-odd manufacturing firms in the Trenton, New Jersey, work area. . . .

"The principal aims of the entire study have been, first, to understand and analyze the employment and wage practices prevailing in the area and, second, to examine the effects of recruitment by the new Fairless Works of U.S. Steel Corporation and other expanding firms upon the hiring, wage, and personnel policies of plants in the area. Important by-products of the study include an analysis of the recruitment problems and policies of new industrial plants and a comparative study of the significance of plant size for industrial relations, as indicated from the experience of the interviewed firms" (From the Introduction).

NOTES

Edwin G. Nourse has been appointed chairman of the American Economic Association nominating committee for the current year. He would appreciate suggestions for officers for next year at as early a date as possible. Such suggestions may be addressed to him at 1785 Massachusetts Avenue, Washington 6, D.C.

The Johns Hopkins University School of Advanced International Studies in Washington, D.C. has opened an overseas branch in Bologna, Italy, to be known as the Bologna Center of the School of Advanced International Studies of The Johns Hopkins University. C. Grove Haines, professor of diplomatic history, will direct the Center and John A. Loftus will be professor of international economics. Scholars from France, Italy, Germany and Austria will make up the teaching staff. The student body will be divided equally among Americans and Europeans. The new Center will provide opportunity for qualifying American graduate students to do graduate study or field research on the four countries of Western Europe—France, Germany, Austria and Italy.

Among recent American Assembly publications of interest to economists are: *Inflation—its Causes, Consequences, and Cures,* based on research-background papers of the Second American Assembly, May 1952; *Economic Security for Americans,* background-research papers and final report of participants in the May 1953 Assembly; and a *Teacher's Manual on Economic Security,* prepared with the Joint Committee on Economic Education with the support of the Committee for Economic Development and Ford Foundation for the teaching of economic security problems in grade and high schools. Individual copies of these publications will be furnished on request to J. H. Chamberlin, Educational Director, The American Assembly, Graduate School of Business, Columbia University, New York 27, N.Y.

Deaths

Stuart Daggett, Flood Professor of Transportation, emeritus, University of California, Berkeley, died December 22, 1954.

Montfort Jones, professor of finance in the School of Business Administration of the University of Pittsburgh. Date of death not reported.

David McCahan, professor of insurance in the Wharton School of Finance and Commerce and president of the American College of Life Underwriters, died June 28, 1954.

J. Melbourne Shortliffe, chairman of the department of economics, Colgate University, prior to retirement in 1947, died December 13, 1954.

G. O. Virtue, professor of economics, emeritus, College of Business Administration, University of Nebraska, died September 9, 1954.

Appointments and Resignations

Theodore Allison has been promoted to chief of the Section of Agreement Records and Analysis in the Wages and Industrial Relations Division of the Bureau of Labor Statistics

C. Canby Balderston has resigned as dean of the Wharton School of Finance and Commerce to become a member of the Board of Governors of the Federal Reserve System.

George B. Baldwin has been appointed executive assistant to the director of the Center for International Studies at Massachusetts Institute of Technology.

Philip M. Banks has been appointed instructor in economics at the Wharton School of Finance and Commerce.

Frank Bass has been appointed assistant professor of marketing at the University of Texas.

Philip W. Bell, of Haverford College, lectured at the Salzburg Seminar in American Studies in the winter term.

Sterie T. Beza has accepted an appointment as instructor in economics at Princeton University for the year 1955-56.

Robert C. Bingham has been appointed instructor in business organization and management and economics in the College of Business Administration, University of Nebraska.

James C. D. Blaine has been promoted to professor of transportation at the University of North Carolina.

Arthur I. Bloomfield, of the Federal Reserve Bank of New York, spent the last three months of 1954 in Indochina on behalf of the Foreign Operations Administration. He also served as U.S. delegate at a meeting of an ECAFE Working Party on financial aspects of economic development.

Roy Blough, who has been principal director of the department of economic affairs of the United Nations, has been named professor of international business at the Columbia University Graduate School of Business, effective July 1955. He will develop a new graduate study program encompassing international business activities.

Joseph H. Bonneville, professor emeritus of New York University, is visiting professor of finance in the School of Business Administration, University of California at Los Angeles, in the current semester.

Philip J. Bourque, formerly at the Wharton School of Finance and Commerce, has been appointed instructor in economics at Muhlenberg College.

Ivor I. Bowen, of the University of Hull, England, is teaching at the University of California, Berkeley in the current semester.

Raymond T. Bowman and William E. Warrington have been elected chairman and secretary, respectively, of the Graduate Group in Economics in the Graduate School of Arts and Sciences, University of Pennsylvania.

Michael Brank, formerly of the University of New Mexico, has been named head of the department of business administration at Quinnipiac College.

Phillips H Brown, of the University of Missouri, has been appointed assistant professor of economics in the College of Business Administration of the University of Arkansas.

Yale Brozen has resumed duties at Northwestern University after spending the past year as visiting professor of economics at the Escola de Sociologia e Politica, Sao Paulo, Brazil and at the Fundaçao Getulio Vargas, Rio de Janeiro.

Thomas A. Budd has been named acting dean of the Wharton School of Finance and Commerce.

George Budzeika has been appointed instructor at Manhattan College

Eugene W. Burgess was visiting professor of industrial relations at Massachusetts Institute of Technology during the fall term 1954-55

John M Chapman, professor of banking, will retire from the Graduate School of Business, Columbia University, in June 1955.

Hollis B. Chenery, on leave of absence from Stanford University, is now in Pakistan with the Mission to Pakistan on Economic Development sponsored by the Ford Foundation and will then go to Italy with the Society for the Development of Southern Italy.

T Hillard Cox, formerly of the Department of Labor, has been appointed lecturer in industry and will serve as management specialist assigned to the Wharton School of Finance and Commerce project at the University of Karachi.

C. M. Crawford has resigned from the University of Florida to accept a position with Mead Johnson & Company in Evanston, Illinois.

Ben T. Curry has been appointed assistant professor of economics at Stetson University.

H. Robert Dodge has been appointed instructor in business organization and management in the College of Business Administration of the University of Nebraska.

Louis A. Dow has been appointed assistant professor of economics in the College of Business Administration of the University of Arkansas.

W. T. Easterbrook, of the University of Toronto, has been appointed Pitt Professor of American History and Institutions at Cambridge University for the session 1955-56.

Seneca Eldredge has been appointed instructor in economics in the College of Business Administration of the University of Nebraska.

VACANCIES AND APPLICATIONS

The Association is glad to render service to applicants who wish to make known their availability for positions in the field of economics and to administrative officers of colleges and universities and to others who are seeking to fill vacancies.

The officers of the Association take no responsibility for making a selection among the applicants or following up the results. The Secretary's Office will merely afford a central point for clearing inquiries; and the *Review* will publish in this section brief description of vacancies announced and of applications submitted (with necessary editorial changes). Since the Association has no other way of knowing whether or not this section is performing a real service, the Secretary would appreciate receiving notification of appointments made as a result of these announcements. It is optional with those submitting such announcements to publish name and address or to use a key number. Deadlines for the four issues of the *Review* are February 1, May 1, August 1, and November 1.

Communications should be addressed to: The Secretary, American Economic Association, Northwestern University, Evanston, Illinois.

Vacancies

Economics, real estate, and insurance: Position open in September, 1955, for assistant or associate professor of economics. Must be able to teach real estate, insurance, and principles of economics. Position is in a small Eastern college specializing in business administration. Applicants should have a Ph.D. or an M.A. and the desire to work towards the Ph.D. Excellent opportunity for advanced graduate work in nearby institutions. P168

Business statistics: Instructor or assistant professor, Southwestern state university. Permanent position to be filled for first semester, 1955-56. Ph.D. preferred but master's degree plus experience will be considerd. Salary $4,200-$5,500 for eleven months, depending upon training and experience. Possibility of higher rank and salary for outstanding candidate. Part-time teaching and part-time statistician in the bureau of business research. P169

Private and public finance: Ph.D. with emphasis in private and public finance for a large coeducational Catholic university in the Midwest, beginning in fall, 1955. Prefer man with some institutional and some teaching experience. P170

Research in economics and investments: Large Eastern company needs a versatile research analyst to work on a wide variety of problems in an established economic-investment research unit. Requirements: At least the M.A., M.S., or M.B.A., preferably Ph.D.; good background in economics with specialization in monetary, investment, or insurance fields; the ability to write well; age not over 35; good personal appearance. This is a research position, but the man must also be able to make a favorable impression on our line executives in both written and oral presentations of his research findings. P171

Accounting, statistics, business law: A leading Southern college will have an opening in September, 1955, for a young man with, or close to, Ph D., to handle courses in accounting, statistics, and business law. Salary and rank depend upon training and experience. P172

International travel opportunity: The Council on Student Travel invites applications for short-term employment as educational directors on trans-Atlantic ships. Required: educators from the following fields: cultural anthropology, art history, international relations and economics, group work, language, philosophy, recreation, sociology. Conversational ability in one or more of the following: French, German, Greek, Italian. Ability to organize extensive educational program with the help of passenger volunteers. From March to December, 1955, the program will be conducted by the Council for students, tourists and migrants traveling aboard two large passenger ships belonging to one of the major lines. These ships sail regularly from New York to European and Mediterranean ports. Job assignments vary from one round-trip sailing to periods of 3-5 months. Compensation for these longer periods of service will be regular salary. For a single round-trip sailing, full or partial passage, depending upon job requirements. All positions allow for time abroad. For further information, application form, write to: Council on Student Travel, (0-1), 179 Broadway, New York 7, N.Y. REctor 2-0936.

Economists Available for Positions

Four years of varied industrial experience; 7 years of teaching experience in leading institutions; some publication. Now teaching in prominent Eastern school (business administration) but is eager to switch to major interest—theoretical economics. No limitations on location. E569

"It's all right...

there's a telephone right here, too"

The man who has a telephone at his elbow in the office appreciates the same convenience in his home.

He knows that running downstairs or from room to room to telephone is an unnecessary waste of time and energy . . . when additional telephones, conveniently placed, cost so little.

Great thing for Mother, too. For telephones in the kitchen and bedroom will save her many steps. And give her greater peace of mind, especially at night when she may be at home alone.

All of this convenience—and safety too—can be yours at small cost for each additional telephone. Just call the business office of your local Bell telephone company.

Bell Telephone System

SERVICE THAT'S WORTH SO MUCH...COSTS SO LITTLE

AN INCOME YOU CAN'T OUTLIVE . . .
AN INCOME THAT KEEPS STEP WITH THE TIMES . . .

You'll need *both* features for your retirement income.

Money put into an annuity during your working years comes back during your retirement as a lifetime income consisting of both principal and interest. But if your annuity doesn't include a hedge against inflation, your retirement income may not give you the purchasing power you expect for your later years.

A pioneering type of annuity, available only to college staff members, now tries to do something about this. Educators may pay up to 50% of their annuity premiums to the new College Retirement Equities Fund; the balance of the premium to TIAA.

The unique CREF variable annuity is based upon common stocks; it will pay more annuity dollars when common stock prices and earnings are high—generally, when the cost of living is high. The TIAA annuity pays a level number of dollars regardless of economic trends, thereby giving greater purchasing power when the cost of living is low. This balanced system tends to hedge against both inflation and deflation

Any employee of a college or university is eligible. Write for further details; we employ no agents.

Don't fail to examine

OUR EXPANDING ECONOMY

the new text for the basic "principles" course

by

RALPH H. BLODGETT

Note especially:

- the unifying theme of long-term growth and development.
- the extensive treatment of national income theory.
- the thorough introduction to business cycles.
- the superior exposition—clear, easy-to-follow, interesting.
- the four chapters on International Economics.
- the three chapters on Comparative Economic Systems.

and the forthcoming

THE PRICE SYSTEM AND RESOURCE ALLOCATION

clearly presented in a text for undergraduate students

by

RICHARD H. LEFTWICH

This step-by-step treatment makes price theory understandable at the undergraduate level. A coherent set of principles and their applications are oriented around the concept of economic efficiency. All phases of market price analysis, product pricing and output, and resource pricing and employment are covered.

new economics text

from prentice-hall, in

an introduction to analysis and policy

by *G. L. Bach,* Carnegie Institute of Technology

Bach's new text aims to help students acquire: (1) the maximum amount of material in economics in the most simple and easy-to-read terms (2) a lasting interest in real-world economic problems (3) a small fundamental and rigorous tool kit for economic analysis (4) an orderly, objective way of thinking about economic policy problems (5) and the ability to use economic analysis in reaching independent thoughtful judgments on major public policy issues.

Over 100 schools have adopted this new text less than one year after publication, including: Columbia University; University of Pennsylvania; University of California, Los Angeles; University of California, Berkeley; Cornell University; Fordham University; Worcester Polytechnic Institute; Indiana University; Carnegie Institute of Technology; University of Illinois; University of Missouri. A *Teacher's Manual* is available upon adoption.

March 1954 6" x 9" 720 pages

---

by *Arthur Robert Burns,* Columbia University

Especially timely because of current interest in the relation between poverty in some countries and their possible political alignment, this new text employs a new approach to explain the differences in economic achievement among various countries. It presents the explanation in terms of the various aspects of scarcity that face all societies. It analyzes the diverse ways in which countries deal with their economic problems. It considers not only nations' general economic and political organization but also their access to resources, methods of organizing production, and policies concerning the distribution of income.

The approach is further distinguished in that it studies primitive, ancient and medieval societies as well as contemporary societies. For this reason, it is the most comprehensive text in its field. Divided into five parts, the text treats—in this order: differences in levels of living; production; productive resources; integration of the productive system; and consumption. Line drawings, charts, graphs, tables and bibliographies increase the text's usefulness.

Spring 1955 6" x 9" approx. 800 pages

by *Herman E. Krooss,* New York University

The American level of living—how it was achieved and what its effects have been—is the central theme of this short economic history of the United States. Emphasizing the factors of production, how they evolved, what they contributed and what they received, the text evaluates the progress we have made in increasing the standard of living. With a topical approach, it explains economic development as a continuous process.

Using simple language, the text explains the nature and background of American economic history and the roles of the land, the population, the farmer, labor and the government in our economy. It studies the evolution of trade unionism, capital accumulation, the development of financial institutions and the contribution of business enterprise. Industrialization and the evolution of the manufacturing industry, domestic and foreign commerce, war, and the business cycle are also analyzed.

Spring 1955 6" x 9" approx. 475 pages

---

by *James N. Morgan,* University of Michigan

Using data on consumer behavior collected by the Survey Research Center, University of Michigan, this next text focuses on consumer choices, both individual and social. It stresses the analytical skills necessary for intelligent consumer choices and interpretation of social-economic problems concerning consumer behavior. Avoiding masses of ephemeral information, the author emphasizes *sources* of information and *methods of using* information.

Starting with the choice between spending and saving, the text examines the social consequences of such decisions and discusses methods whereby a consumer can make these decisions for himself. Whole chapters are devoted to insurance against risks, medical care, and housing. In each case the individual's problems are discussed, then the consequent problems faced by the whole economy. Other major expenditures, government and other protections for the consumer, and economic problems of direct concern to the consumer are also examined. Finally, the text discusses the problem of maximizing consumer satisfaction.

April 1955 5⅜" x 8⅜" approx. 448 pages

ELEMENTARY ECONOMICS, 2nd Edition 1954

by *J. A. Nordin,* Iowa State College; and *Virgil Salera*

Centered around the development of responsible citizenship and decision making, the new second edition of this popular text employs the national income approach. Chapters on national income, prices, banks, wages, economic stabilization, social security, and international economics reflect the latest field research and developments in economics. The authors' clear writing style, coupled with end of chapter questions, glossary and cases to illustrate the technical material, greatly aids student comprehension. An *Instructor's Manual and Objective Tests,* available on adoption, increases the text's value.

April 1954 — 5⅝" x 8⅜" — 783 pages

COMPETITION AND ITS REGULATION

by *Andreas G. Papandreou* and *John T. Wheeler,*
both of the University of Minnesota

Using classroom tested materials, this new text gives a comprehensive statement and vigorous analysis of competition and our anti-trust policy. It employs the theory of games in developing a theory of competitive behavior and in formulating criteria for evaluation of public policy in the anti-trust field. It analyzes the meaning of workable competition and integrates current developments in economic analysis with institutional description and recent legal interpretation in the anti-trust field

September 1954 — 5⅝" x 8⅜" — 504 pages

ECONOMIC DEVELOPMENT: Principles and Patterns

edited by *Harold F. Williamson,* Northwestern University,
and *John A. Buttrick,* University of Minnesota

Reflecting current interest in raising living standards in underdeveloped areas, the text's thirteen contributors chart the strategic factors in development, regional economics, and social and economic change. Part I covers the various aspects of the development process. Part II presents three case histories of economic development in India, Japan, and Mexico.

August 1954 — 6" x 9" — 588 pages

RUSSIA'S SOVIET ECONOMY, 2nd Edition 1954

by *Harry Schwartz,* Specialist on Soviet Affairs, The New York Times,
formerly, Syracuse University

An objective evaluation of the strength and effectiveness of the Soviet economy, the second edition is the only comprehensive, up-to-date survey of Russia's economy—its origins, organization, and operation—available in English. Main feature of revision is the up-dating of material, principally in the light of the events of the last four years.

THE AMERICAN ECONOMIC REVIEW

VOL. XLV | MAY, 1955 | NUMBER 2

PAPERS AND PROCEEDINGS

OF THE

Sixty-seventh Annual Meeting

OF THE

AMERICAN ECONOMIC ASSOCIATION

Detroit, Michigan, December 28-30, 1954

Edited by James Washington Bell, Secretary of the Association

and

Gertrude Tait, Executive Assistant

PRINTED BY GEORGE BANTA PUBLISHING COMPANY

Publication Office: 450 Ahnaip Street, Menasha, Wisconsin

Executive Office: American Economic Association, Northwestern University, Evanston, Illinois

Inquiries and other communications regarding membership, meetings, and the general affairs of the Association, as well as orders for publications, should be addressed to Dr James Washington Bell, Secretary of the American Economic Association, Northwestern University, Evanston, Illinois.

Changes of address should be sent to the Secretary at the Executive Office at Northwestern University, Evanston, Illinois. To be effective, notice must reach the office by the 15th of the month previous to the month of publication. The Association cannot be responsible for copies lost due to failure to report change of address in time.

Entered at the post office at Menasha, Wisconsin, as second class matter Acceptance for mailing at special rate of postage under the provisions of Sec 34-40 Par. (D) provided for in the Act of February 28, 1925, embodied in paragraph 4, section 412, P. L. and R., authorized September 13, 1928.

The *American Economic Review* is published five times a year, in March, May, June, September, and December, and is sent to all members of the American Economic Association as one of the privileges of membership, $5 00 of the annual membership dues of $6 00 being in payment of a year's subscription to the publication. Printed in U S.A.

PRICE, $2.50

PROGRAM OF THE SIXTY-SEVENTH ANNUAL MEETING OF THE AMERICAN ECONOMIC ASSOCIATION

Detroit, Michigan, December 28-30, 1954

No central theme has been sought for in the program this year. The attempt has been rather to provide opportunity for presenting results of current research, with preference in selection of papers given to the younger scholars who have not participated actively in the program in recent years.

Tuesday, December 28, 1954

10:00 A.M.
Meeting of the Executive Committee

12:30 P.M.
Luncheon Meeting of the Executive Committee

2:30 P.M.
International Flow of Economic Ideas
Chairman: V. W. BLADEN, University of Toronto
Papers: T. W. HUTCHISON, University of London; JOSEPH DORFMAN, Columbia University
Discussion: J. M. LETICHE, University of California; G. H HILDEBRAND, University of California at Los Angeles

Long-term Trends in Capital Formation and Financing (joint session with the American Finance Associaiton)[1]
Chairman: J. J. O'LEARY, Life Insurance Association of America
Papers: A. S. TOSTLEBE, Wooster College; SERGEI DOBROVOLSKY, Wayne University; M. J. ULMER, American University
Discussion: G. T. CONKLIN, Guardian Life Insurance Company; ELI SHAPIRO, Massachusetts Institute of Technology

Regional Economics
Chairman: WALTER ISARD, Massachusetts Institute of Technology
Papers: J. V KRUTILLA, Tennessee Valley Authority; F. T. MOORE, RAND Corporation
Discussion: PHILIP NEFF, University of California at Los Angeles; LEON MOSES, Harvard University; F. A. HANNA, Duke University

8:30 P.M.
Concepts of Competition and Monopoly
Chairman: CLAIR WILCOX, Swarthmore College
Papers: J. M. CLARK, Columbia University; SIDNEY WEINTRAUB, University of Pennsylvania
Discussion: FRITZ MACHLUP, Johns Hopkins University; KERMIT GORDON, Williams College; GARDNER ACKLEY, University of Michigan

Current Problems in Agricultural Economics
Chairman T. W. SCHULTZ, University of Chicago
Papers: E. O. HEADY, Iowa State College; MARTIN BRONFENBRENNER, University of Wisconsin
Discussion: D. G. JOHNSON, University of Chicago; D. R. KALDOR, Iowa State College

Models of Economic Growth (joint session with the Econometric Society)
Chairman: R. W. GOLDSMITH, National Bureau of Economic Research
Papers: STEFAN VALAVANIS-VAIL, University of Michigan; JOHN POWERS, Stanford University
Discussion: E. D. DOMAR, Johns Hopkins University; T. C. SCHELLING, Yale University

Pricing in Transportation and Public Utilities
Chairman: M. L. FAIR, Tulane University
Papers: W. S. VICKREY, Columbia University; F. K. EDWARDS, National Coal Association
Discussion: E. W. CLEMENS, University of Maryland; J. C. NELSON, Washington State College

[1] To be published in the *Journal* of the American Finance Association.

Wednesday, December 29, 1954

9:30 A.M.

Development Policy in Underdeveloped Countries
Chairman: MAX MILLIKAN, Massachusetts Institute of Technology
Papers: H. B. CHENERY, Stanford University; W. H. NICHOLLS, Vanderbilt University
Discussion: E. E. HAGEN, Massachusetts Institute of Technology; WILFRED MALENBAUM, Massachusetts Institute of Technology

Economic Stabilization, Forecasting, and the Political Process
Chairman: ROY BLOUGH, United Nations
Papers: R. C. TURNER, Indiana University; S. K. BAILEY, Princeton University
Discussion: SOLOMON BARKIN, Textile Workers Union of America; H. R. BOWEN, Williams College; R. A. LESTER, Princeton University; T. G. MACGOWAN,[1] Firestone Tire and Rubber Company

The Impact of Antitrust Laws
Chairman: R. B. HEFLEBOWER, Northwestern University
Papers: S. N. WHITNEY, Twentieth Century Fund; J. W. MCKIE, Vanderbilt University; LOUIS MARENGO, Washington, D.C.
Discussion: WALTER ADAMS, Michigan State College; S. M. LOESCHER, Indiana University; J. H. STAUSS, Grinnell College

12:30 P.M.

Luncheon Meeting (joint session with the American Finance Association)[1]
Speaker: T. O. YNTEMA, Ford Motor Company

2:30 P.M.

Economic Development: Case Studies
Chairman: ARTHUR SMITHIES, Harvard University
Papers: J. H. YOUNG, Yale University; MARVIN FRANKEL, University of Illinois
Discussion: D. H. STEINTHORSON, Bank of Canada; DUANE EVANS, Bureau of Labor Statistics

Economic Research and Public Policy
Chairman: GERHARD COLM, National Planning Association
Papers: J. A. LIVINGSTON, *Philadelphia Bulletin*
Discussion: EWAN CLAGUE, Bureau of Labor Statistics; G. W. ENSLEY, Joint Committee on the Economic Report; STANLEY LEBERGOTT, Bureau of the Budget; BERT SEIDMAN, American Federation of Labor; M. A. WATSON, National Shoe Manufacturers Association

Taxation and Income Distribution
Chairman: H. M GROVES, University of Wisconsin
Papers: D M HOLLAND, National Bureau of Economic Research; P J. STRAYER, Princeton University
Discussion: W. W. HELLER, University of Minnesota; R. E. SLITOR, Washington, D C

8:30 P.M.

Presidential Address
Chairman: I L. SHARFMAN, University of Michigan
Paper: SIMON KUZNETS,[2] Johns Hopkins University

Thursday, December 30, 1954

9:30 A.M.

Urbanization and Industrialization of the Labor Force in a Developing Economy (joint session with the Industrial Relations Research Association)
Chairman: L. G. REYNOLDS, Yale University
Papers: W. E. MOORE, Princeton University; B F HOSELITZ, University of Chicago
Discussion: G. B. BALDWIN, Massachusetts Institute of Technology; W. H. KNOWLES, Michigan State College; SIMON ROTTENBERG, University of Chicago

Cyclical Experience in the Postwar Period
Chairman: GARDNER ACKLEY, University of Michigan
Papers: RENDIGS FELS, Vanderbilt University; K. D. ROOSE, Oberlin College
Discussion: JOHN LINTNER, Harvard University; DANIEL HAMBERG, University of Maryland; E C. HALD, University of Washington

Research on the Business Firm
Chairman: H. R. BOWEN, Williams College
Papers: EDITH PENROSE, Johns Hopkins University; C. A. HICKMAN, North Carolina State College
Discussion: ALBERT LAUTERBACH, Sarah Lawrence College; W. W. COOPER, Carnegie Institute of Technology

[1] No manuscript received.

2:30 P.M.

Long-term Trends in International Trade

Chairman: FRITZ MACHLUP, Johns Hopkins University

Papers: R. E. BALDWIN, Harvard University; H. G. AUBREY, Federal Reserve Bank of New York

Discussion: C. P. KINDLEBERGER, Massachusetts Institute of Technology; THEODORE MORGAN, University of Wisconsin; A. C. HARBERGER, University of Chicago

Price and Wage Flexibility (joint session with the Industrial Relations Research Association)

Chairman: R. T. BOWMAN, University of Pennsylvania

Papers: J. M. BLAIR, Federal Trade Commission; K. E. POOLE, Northwestern University

Discussion: GIDEON ROSENBLUTH, Queen's University; F. C. PIERSON, Swarthmore College

Debt Management and Monetary Policy

Chairman: L. H. SELTZER, Wayne University

Papers: M. A. ROBINSON, Dartmouth College; C. R. YOUNGDAHL, Federal Reserve Board

Discussion: A. G. HART, Columbia University; E. R. ROLPH, University of California

5:00 P.M.

Business Meeting

6:00 P.M.

Dinner Meeting of the Executive Committee

THE purpose of the American Economic Association, according to its charter, is the encouragement of economic research, the issue of publications on economic subjects, and the encouragement of perfect freedom of economic discussion. The Association as such takes no partisan attitude, nor does it commit its members to any position on practical economic questions. It is the organ of no party, sect, or institution. Persons of all shades of economic opinion are found among its members, and widely different issues are given a hearing in its annual meetings and through its publications. The Association, therefore, assumes no responsibility for the opinions expressed by those who participate in its meetings. Needless to say, the papers presented are the personal opinions of the authors and do not commit the organizations or institutions with which they are associated.

JAMES WASHINGTON BELL
Secretary

INTERNATIONAL FLOW OF ECONOMIC IDEAS

INSULARITY AND COSMOPOLITANISM IN ECONOMIC IDEAS, 1870-1914

By T. W. HUTCHISON[1]
University of London

I

The activities of economists—what they do and how and why they do it—are of at least as much interest and importance as the activities of the people economists themselves study: businessmen, housewives, bankers, finance ministers, and trade-union leaders. Although economists may—for better or for worse—not always have the effects on the politico-economic world around them which they intend or desire to have, they do directly and indirectly, often after long lags and much "friction," exercise some extremely important effects on various kinds of economic processes. A complete explanation of many types of economic processes cannot be given unless this explanation, or the model being used, takes account of the tides, gusts, streams, and flows of doctrines, opinions, and prejudices emanating from economists. So the study of economic processes must include the study of economists, or of the origin, flow, and development of their ideas—for one can hardly separate the study of the origin of ideas from that of the change and flow of ideas. Such a study includes as well as all the processes of changes in ideas, and how ideas originate, also the processes by which they succeed, catch on, and dominate their time; it includes also the lags and impediments in the flow of ideas, both across and within national and linguistic frontiers, and the questions of whether and in what sense there can be said to be progress in the flow of economic ideas, or whether there is a circular or pendulum movement, and how far this movement is the result to some extent of fashion—since the adjective "fashionable," in a faintly pejorative sense, is one of the most frequently encountered adjectives in our economic journals. All such questions lie in a vast field covered as yet only, on the one hand, by fairly casual unsystematized individual observations and, on the other hand, by a few wildly oversimplified and overcomprehensive generalizations (for example, the cruder sorts of Marxist generali-

[1] I am much indebted to Professor G. J. Stigler for valuable help in the conception and execution of this paper, though, of course, he does not bear any responsibility for its contents.

zation). It is in a minute subsection of this vast, amorphous, uncategorised field that this paper and this section of the Association's program, "The International Flow of Economic Ideas," belongs. It is very tempting to continue this general stage setting: indeed it would be easy to go on with the stage setting so long that there would be no time for the little play I am supposed to be putting on. But I must turn now to my allotted task and to the state of economic ideas and the international flow thereof, round about 1870.

II

In reviewing the international flow of economic ideas between 1870 and 1914, I must, from limitations of space and knowledge, take a rather Anglo-centric line, and consider primarily the flow into and propagation in Britain of economic ideas from abroad, leaving out movements and conflicts between other European centers: for example, between Austria and Lausanne and between Austria and Germany. The story seems to fall fairly naturally into two or three main phases. The first phase, in which Jevons is the outstanding figure, is that of the seventies when we have the discovery, for British economists especially, of the great French and German predecessors of marginal analysis—Cournot, Dupuit, von Thünen, and Gossen—some twenty, thirty, or forty years after the first publication of their works. At the same time we have also the contemporary interchange between Jevons and Walras. After something of a lull in the eighties, towards the end of which the ideas of the leading Austrian economists first became widely known in England, we reach in the nineties the high point in our period of the cosmopolitan interchange and development of economic ideas, notably concerning the theory of the consumer and the theory of marginal productivity. In this international interchange of the nineties English economists play a certain part, but not relatively a very large or leading part. Then in the final phase, from the nineties down to 1914, contemporary with the predominance of Marshall and his school, the flow of economic ideas into Britain from abroad, and their acceptance and appreciation, dries up very considerably, although there were still, all the time, many new ideas and refinements being advanced in Lausanne, Italy, Austria, and Germany, notably on the subjects of the consumer, welfare, interest, money, and business cycles.

The marginal utility theory of value was not, of course, discovered in 1871-74. Both the component ideas (especially that of the relation between utility and value but also that of the marginal concept, as well as the combination of the two ideas in the marginal utility theory of value) had had a number of previous expounders. The years 1871

to 1874 are simply the time from which hindsightedly and *ex post* we can recognize one of the major fundamental turning points in economic ideas: first, there follows the widespread application of the marginal concept especially to microeconomic maximization formulae; secondly—and this applies to Britain only—we can date in 1871 the end of roughly a century of that perhaps slightly overconfident, doctrinaire, and distorted Anglo-classical overemphasis on the role of labor and cost of production in value; and we have something of a return back to the mainstream of balanced European thinking about value since Aristotle, in which a full and explicit role for the demand side had never been long or seriously left out of account.

The three men of 1871-74 were not reacting to, or stimulated by, any common cosmopolitan intellectual situation brought about by an active international interchange of ideas about the problem of value (or any other economic problem). In fact, for several decades there had been hardly a trickle, much less a flow, of economic ideas into Britain from elsewhere, and of course the internal flow of ideas in Britain itself had almost completely dried up. In the judgment of the most orthodox and overwhelmingly influential authorities, the subject of value had been settled once and for all. I think it can be said that the more narrowly economic theories in Mill's *Principles of Political Economy* show hardly any positive traces of any idea from any French, Italian, German, or Austrian source, except in regard to J. B. Say's theory of markets (and certainly *not* in regard to Say's quite sensible treatment of value and distribution). Though J. E. Cairnes wrote a critical essay on Bastiat, from his *Leading Principles* (1874) it appears that pretty well no one outside Britain had ever had an idea on the central doctrines of economic theory that was worth mentioning (apart, again, from Say's theory of markets). Senior had been to some extent a notable exception. He had studied Hermann's work and had derived from it at least a certain confirmation or encouragement in his departure from some of the main doctrines of Ricardian orthodoxy. If, of course, J. S. Mill had had time in the rather brief periods he later devoted to political economy to study what Taussig described as "the incisive and original" work of Hermann, with its "high intellectual quality," he might have been moved to rethink his ideas about the wages-fund doctrine some thirty-seven years before he eventually did so. Of course some of the "underground" English utility theorists such as Banfield, and perhaps Jennings, had learnt from European economists. In fact, to call attention to the work of Hermann and Rossi (J. B. Say's successor in Paris) had been the proclaimed primary intention of Banfield's lectures at Cambridge in 1844. But as regards the orthodox and overwhelmingly dominant treat-

ment of the fundamentals of economic theory, the position for a quarter of a century or more before 1871 could have been summed up in the celebrated London newspaper headline: "Fog in the English Channel, Continent Isolated." As Taussig put it: "The insular condition of social and political speculation in Great Britain in the middle of the century, and the stagnation of economic thought in particular, prevented a breath of influence from reaching English thinkers." (*Wages and Capital*, page 266.) Though this generalization may or may not be questionable as regards social and political ideas, it is surely well founded with regard to economic theories. We might, however, mention in passing one peculiar but vastly consequential case of the international flow of economic ideas that was taking place in mid-century in the British Museum library; that is, the discovery by Karl Marx of a framework for his economic doctrines in the works of Smith and Ricardo.

Thus with the international flow of economic ideas virtually at a standstill, the three men of 1871-74—and this applies to Menger and Walras as well as to Jevons—each reached his discovery by his own original and mainly national route. There is, therefore, quite a measure of coincidence in the almost simultaneous publication of their ideas by Jevons, Menger, and Walras, though the increasing occurrence of the isolated publications of the marginal utility idea, or of ideas pretty near it, made such a double or treble coincidence in dates almost inevitable sooner or later. And. of course, there is in any case nothing of a coincidence in the fact that this threefold, nearly simultaneous, publication, by three university professors, became recognizable in retrospect as that major turning point when enough force was finally generated gradually to get started a cumulative process sufficient to mark what can be seen now as the opening of a new period in economic thought. For such a major shift to get under way, at first very gradually, some such threefold spark was necessary. None of the numerous previous isolated individual flashes had been enough to get an ideological chain reaction or cumulative process started, or to get the torch burning sufficiently steadily so that it could not be neglected or quenched. As Walras proudly reported to his aged master Cournot in 1874: "M. Jevons et moi avons amené la question à un point tel qu'elle ne pourra bientôt plus être écartée par les économistes."

Let me develop rather further and qualify slightly this generalization about the separate national settings in which Jevons, Menger, and Walras developed their ideas. Jevons' marginal utility theory was the fruit of his own originality stimulated by his study of Lardner, Bentham, and perhaps Jennings. Through Lardner there came from France possibly some extremely diluted and selective traces of Cour-

not's monopoly analysis. Menger's theory was the product of his own originality building mainly on the works of Hermann, Schaeffle, and other Germans, including perhaps Mangoldt. And Walras was indebted to his father, to his father's classmate Cournot, and, of course, beyond that to the traditional current of French thought on value and distribution going back through J. B. Say to Turgot, Condillac, and Galiani. These extremely brief and familiar statements do really seem to summarize all that is worth summarizing, and it would be pointless, and perhaps even quite misleading for our purpose, to explore much further. Though there may well have been other particular institutional influences relatable to the ideas of Jevons or Menger or Walras, *separately,* we can only think of one *institutional* influence which may have been common to the background both of Jevons and Walras, and which was present in the first economic problem Jevons wrote about, that of the railways of New South Wales, at the same time as he was studying Lardner's book on *Railway Economy.* This institutional influence may at a later stage perhaps have to some extent acted on Walras through Dupuit, though Walras does not seem to have studied Dupuit till well on in the seventies and then not, at first at any rate, to have appreciated the significance of his work. This common institutional background influence was that of the growing problems, in the second half of the century, of the pricing policies of public utilities especially in transport, with their large fixed and comparatively small variable costs, where the divergencies between marginal and average cost and marginal and average revenue were so important and inescapable. For those who hanker after some "exogenous" explanation of the development of marginal analysis (that is, an explanation in terms of the problems and institutions of the contemporary economic world), there is this consolation prize, such as it is. But the discovery, and above all the subsequent elaboration, of marginal analysis is surely an example of a predominantly "endogenous," logical. intellectual development out of the internal theoretical problems of economic analysis itself, at a considerable level of abstraction. It has also been argued that the marginal utility theory was developed as a bourgeois counterblast to Marxian economic theory. Though subsequently Wicksteed, Böhm-Bawerk, and Pareto made some use of the subjective theory in this way, there does not seem to be even a grain of truth in this argument applicable to the original triumvirate of 1871-74, or to their motives, conscious or unconscious.

The increase in the international flow of economic ideas in the seventies—slight and qualified as compared with what came later but very marked as compared with what had gone before—may be traceable to two interconnected and mutually reinforcing factors. First,

there is the relatively much more abstract mathematical nature of the new ideas on value, and, secondly, there is the gradually increasing importance of the academic scholar in the world of economists and the increasingly professional intellectual status and standards of the pioneers of marginal analysis and of the whole neoclassical period. The marginal formulae were very easily susceptible to mathematical modes of expression; that is, to formulation in an international language. Obviously today *Econometrica* (though in some ways the least intelligible of our magazines) is clearly the most cosmopolitan and internationally or interlinguistically the most intelligible. Jevons' enthusiasm for the mathematical method may perhaps seem today a little quaint considering his comparatively very elementary use of it. But Marshall, of course, knew just what he meant and was making a significant comparison with previous economic theories when he wrote of the work of Carl Menger—ironically a virulent opponent of the mathematical method—that it, "though not making use of the mathematical language is distinctly mathematical in tone" (*Principles*, first edition, page 149). Secondly, with economics becoming increasingly a subject for university scholars, it became more widely regarded as a duty, if not universally followed as a practice, to explore and refer to work in other languages by way of a professional scholarly obligation not felt or fulfilled to the same extent by the often less academic political economists of preceding generations. The example of German scholarship was of some importance here.

We may take as marking the opening of this new international flow of economic ideas the moment in May, 1874, when Walras and Jevons exchanged letters, though Jevons had read Walras' work a short time before they corresponded. I cannot fix with precise certainty when it was that the works of Menger or of other Austrians were first noticed in England or outside Austria and Germany. In any case, Jevons never saw Menger's work, and certainly no considerable or wide attention was paid to any Austrian ideas in Britain till the second half of the eighties. But it was in 1879 in the Preface to the second edition of his *Theory of Political Economy* that Jevons set new standards of cosmopolitan scholarship and intellectual receptiveness, especially for British economists, by searching out with unprecedented conscientiousness all the works of predecessors and contemporaries which had anticipated or shared in his own new ideas. This Preface is, in its new standards of scholarly presentation, almost as outstanding and novel an achievement, in its way, as his ideas on marginal utility had been in the first edition. Of course there had some time before been McCulloch's historical and bibliographical work. But the bibliographical listing of all known writings on political economy and its various

branches is something quite different from the international documentation of a particular new idea, not only in its origins but in its contemporary treatments, such as Jevons achieved in his Preface. The former is largely an *ex post* record; the latter serves much more to create a contemporary international market in ideas and to make advances in the subject to some extent a process of international cooperation.

Cournot, Dupuit, Gossen, Léon and August Walras, von Thünen (and incidentally William Whewell, of Cambridge) are here all given, in some cases absolutely their first recognition by an English economist, in others certainly their first sympathetic and illuminating reference in English. Jevons threw open the windows on a whole vast new landscape of economic ideas, including the writings of one or two of those now recognized as among the most fundamental seminal pioneers in the history of the subject. Naturally Jevons himself did not, and could not reasonably have been expected to, take in anything like the full significance of the vast range of work of the half-dozen great economists he presents.

There is one detail here over which we should like to linger for a moment, and that is the slight mystery which seems to hang about Jevons' reference to the work which some economists might take today to be the greatest and most original of all pioneer achievements; that is, Cournot's *Recherches.* The question arises as to who was the first economist in Britain to appreciate something of the vast significance of Cournot's *Recherches.* Jevons says in his Preface (page xxix): "This work must occupy a remarkable position in the history of the subject. It is strange that it should have remained for me among Englishmen to discover its value." This statement seems as it stands to be inaccurate, and rather curiously inaccurate. Twenty to thirty years later, Marshall was to write to J. B. Clark that "I fancy I read Cournot in 1868," and Keynes says that the *Recherches* "must have come into his hands some time between 1867 and 1870." This of course gives Marshall a priority Jevons could not have known about, except—and it is curious that Jevons did not seem to have noticed this—that Marshall did make a single fleeting mention of the *Recherches* in his article, prominently published in the *Fortnightly Review* in 1876, on "Mr. Mill's Theory of Value." But it is certainly true that no one could have appreciated from Marshall's passing reference the vast significance Cournot's book was having both for Marshall's own work and for all subsequent economic thought. Another rather curious question is posed by Jevons' mention that the man who had put him on to the possible significance of Cournot was the mathematician Todhunter, who was, or had recently been, a fel-

low of St. Johns—Marshall's own college. Todhunter himself had not seen the *Recherches*, but in 1875 suggested its significance to Jevons, who had obtained a copy in 1872 without studying it carefully till some years later. Now it is ruled out that it was Marshall who put his fellow Johnian mathematician Todhunter on to Cournot, because Todhunter is quoted by Jevons as writing that "when I have mentioned the title, I never found any person who had read the book." Were these two fellow Johnians, both interested in the application of mathematics to economics, not on speaking terms? It is indeed an oddity for students of the flow of ideas, international or national, that the width of the high table at St. Johns College was, apparently, for a few years at any rate, a sufficient impediment to the propagation in Britain of the ideas of one of the outstandingly original and consequential writers in the history of economic thought. So here with regard to the discovery of Cournot in Britain is a further point of contention for protagonists—if there are any left—of the relative priorities and achievements of Jevons and Marshall. Anyhow, it is certain that Jevons first fully brought Cournot's work (as well as Dupuit's, Gossen's, von Thünen's, and Walras') prominently and inescapably to the attention of British economists. Marshall on the other hand had been quietly studying Cournot some years before, but before 1890 made one single fleeting reference in 1876 to the work which had, as Marshall himself put it, "directed the forms of my thought." We might add that it seems possible that the full significance of Cournot's work was first appreciated in America before it was in Britain. Anyhow, as Professor Dorfman has pointed out to me, Simon Newcomb in his review of Jevons' *Theory of Political Economy* in the *North American Review* for 1872, while warmly welcoming Jevons' work (in this respect being almost alone among Jevons' reviewers in English) nevertheless places it well below the supreme class which he considered Cournot's *Recherches* to occupy—which work was obviously thoroughly well known to and appreciated by him. Jevons gives no sign, as far as I know, of ever having seen this remarkable review of Newcomb's, though Newcomb is mentioned in Jevons' Preface to his second edition of the *Theory*.

The international flow of economic ideas set going by Jevons and Walras was followed by something of a lull in the eighties, which, at any rate in Britain, seems on the surface to have been rather a lean period, though it was, of course, in this decade that Marshall's *Principles* was being written and though Edgeworth's *Mathematical Psychics* of 1881 was soon to have an important international influence. The eighties are, however, the great decade of the original Austrian triumvirate, and towards the end of it their works—thanks

to Smart, Bonar, and others—became widely known in Britain and elsewhere. In the early nineties, Böhm-Bawerk's two volumes and Wieser's *Natural Value* appeared in English translations, as had Pantaleoni's *Pure Economics* in 1889, a work in which the Austrian influence was strong. So far as I have ascertained, these, with the possible addition of Cassel's *Nature and Necessity of Interest,* are the only major neoclassical translations into English in our period. (The Fisher edition of Cournot in 1898 is in rather a different category, as are the English editions of Marx.)

Towards the end of the eighties and through the nineties, we come to the peak decade in the flow and interchange of ideas in the neoclassical period. We have the development of the marginal productivity theory of distribution, which had of course its English and German predecessors but which was now perfected, refined, and widely accepted. We have also a new analysis of consumers' equilibrium and new debates over the theory of capital; and all these advances are carried through by a wide international exchange of ideas. In their writings of that decade or of a few years previously, Edgeworth, Wicksteed, Auspitz and Lieben, Wieser, Böhm-Bawerk, Wicksell, Walras, Pareto, Barone, and Fisher all drew on a broad, internationally known literature, made up to a large extent of their own writings. Works like Wicksell's *Value, Capital and Rent* and Pareto's *Cours,* though they contain their own particular original ideas, are constructed essentially on the basis of a wide, eclectic, cosmopolitan reading of their contemporaries and immediate predecessors. The marginal productivity theory was, therefore, developed in a very different setting to that in which the marginal utility pioneers of 1871 had worked out their ideas. We must omit the details of this decade, but we must call attention to one fact. Although Edgeworth and Wicksteed made very important contributions to the international development in the nineties of the theory of distribution and though to a considerable extent they followed Jevons in the international breadth of their reading and comprehension of contemporary European writings, patches of fog were again noticeable over the English Channel and the Continent was again partially isolated. There were important ideas, first broached in Europe in the nineties or soon after the turn of the century, on the subject of the theory of the consumer, of welfare or "ophelimity" economics, of interest, money, and business cycles, which were not to find a reception in Britain for the best part of two, three, or even four decades. I refer of course to what are now recognized as some of the most celebrated contributions to economics of Walras, Pareto, Auspitz and Lieben, Fisher, Wicksell, Spiethoff, Mises, and Schumpeter.

III

How did this reaction come about? After Jevons had, shortly before, opened up such great vistas in respect of French and German economic ideas, how and why was it that a so much more stay-at-home regime so soon supervened in Britain? We must first get an idea of the restricted extent of the flow of economic ideas from abroad after the early nineties. After 1893 there was, in the period we are concerned with, no further translation into English of any major neoclassical book of economic theory (except for Cassel's on *Interest,* already mentioned). One might have imagined that the establishment of the specialist *Economic Journal* in 1891 might have marked a renewed attempt to expand and maintain, in the tradition of Jevons' Preface, the flow of ideas from the Continent which, as we have seen, was then almost teeming with new developments in one branch or another of economic theory. Edgeworth, the editor, was certainly a greater master of languages, including the international language of mathematics, than Jevons had been, and kept in close, though not always very sympathetic, touch with Austrian, French, and Italian economists. But either for Edgeworth's own reasons or because he deferred to the judgment of his senior colleague, the *Economic Journal* in what it included and what it excluded (especially in what it excluded) cannot be said in our period to have contributed notably to the international flow of economic ideas. Looking through the volumes of the first twenty-five years, we find a single article a piece by each of the three leading Austrians, Menger's being on the subject of money, with certainly quite extensive reviews of the new works of Wieser and Böhm-Bawerk. But we find no article by Walras nor a single review of any work by him, though—as Professor Jaffé has shown me that his correspondence reveals—Walras was most keen that all or some of his work should appear in English and actually pressed it upon Edgeworth. No contribution from Barone appears, though according to a letter of his to Walras, which Professor Jaffé has kindly informed me of and copied out for me, he submitted an article on marginal productivity at Edgeworth's request only to have it rejected. "Ma note n'a pas le bonheur d'être agreé pas le pontiffe des économistes anglais, M. Marshall, et le pauvre M. Edgeworth s'est trouvé dans l'embarras!" Pareto contributes no article and he appears only once briefly as a reviewer in 1912 and once as a "reviewee"—as regards his *Cours* in 1896. There is a single famous article by Wicksell in 1907, which seems to have roused very little attention or understanding at the time, and when his *Lectures* were published in German in 1913 they were dealt with in a single twenty-line paragraph. It is true that when in the years just before the first

World War the business cycle became increasingly the subject of systematic study in Britain, some—often rather critical—notice was taken of the writings in French of such predecessors as Tugan-Baranovsky and Aftalion, though the ideas of Spiethoff and also of Schumpeter hardly received the attention which in subsequent decades they have been recognized as deserving.

How are we to explain these considerable limitations to the flow of economic ideas into Britain, this lack of interest in and receptiveness to many of the best ideas of Walras, Pareto, Wicksell and others—many of them ideas which in the decades since seem to have won out as among the best of their time? We can only try to indicate some of the broad considerations and factors.

By 1900, the superstructure of neoclassical marginal analysis was complete in its main outlines, and a considerable measure of unification and agreement had been fairly easily reached as to this superstructure of formulae. That part of the main outline where nothing like agreement or unification was attained and where these were, of course, far more difficult of attainment concerned basic philosophical or methodological questions: for example, regarding the mathematical method, and regarding the utility and social utility concepts. These differences regarding the utility concept still persisted, and they led to diverging analyses of the consumer and to some extent of welfare economics, which if not very different in their conclusions—they were in any case pretty well void of empirical content—were based on very different concepts and techniques. Separate analyses thus came into being, divided by a quagmire of philosophical-methodological conundrums and terminological dogmas over which no agreed bridge could be constructed. Here were issues certainly not capable of any easy, generally acceptable resolution by the precise international language and criteria of mathematical or quasi-mathematical analysis, such as had served to produce the more or less common agreed superstructure. Moreover, the spectacle of the recent Austro-German *Methodenstreit* was certainly not one which could arouse much hope of enlightenment through an international debate of the methodological issues at stake.

Moreover, at the opening of this century that curious intellectual-psychological-sociological phenomenon, the Academic School, was at the height of its influence, cohesion, and prestige, with its two outstanding examples, the Austrian and Marshallian Schools, which were also, of course, largely national schools. Though much of the superstructure of their systems could be and was presented in easily reconcilable terms, these "school" systems rested on tenaciously maintained, if not always energetically explored, terminological dogmas, con-

cepts, and philosophical presuppositions, which turned them somewhat into impermeable, monolithic, intellectual structures in the nature of ideologies, insusceptible to modification or adjustment by any piecemeal give-and-take of ideas, national or international. The Austrian School, though by no means monolithic in all its doctrines, was agreed as to its original leaders in its vigorous rejection of all forms of mathematical analysis and expression. Menger and Böhm-Bawerk even rejected such a fundamental mathematical notion as that of the mutual determination and interdependence of economic quantities, and held dogmatically to a sort of monocausal theorizing which prevented the intellectual bridges being built over which a mutual permeation of their system of thought with the systems of Marshall or Lausanne could have come about. Those Austrians who were sympathetic to mathematical methods or receptive to non-Austrian ideas, such as Auspitz and Lieben and Schumpeter, soon became more or less outcasts from the Austrian School proper.

On the other hand, the Marshallian School held both to a number of well-known but specifically Marshallian concepts and assumptions, as well as to a sort of attenuated Anglican utilitarianism, or "utility-arianism," which it was not considered worth while to explore beyond, argue over, or re-examine. In his recent review, Professor Sir Dennis Robertson recognized this topic "on the face of it as of some importance," but as one, he goes on, which "when I started to read economics at Cambridge in 1910, it was not, I think, fashionable among us to think much about. . . . To us, I think, it seemed a topic more suitable for discussion by Germans than by Englishmen. We thought we knew pretty well what sort of things we wanted to know about, and were glad enough to take the counsel given by Marshall himself near the beginning of the *Principles*, 'the less we concern ourselves with scholastic enquiries as to whether a certain consideration comes within the scope of economics the better.'" (*Utility and All That* [1951], page 14.) British economists under the leadership of Marshall who followed out this line of approach were naturally cut off from much interest in economic ideas and analysis, whether emanating from Germans or from others, which proceeded from different conceptions of "what sort of things we wanted to know about," or, for example, from different conceptions of the significance and legitimacy of the utility and welfare concepts.

After 1890, Marshall's *Principles* and his school of thought soon rose to a position of almost complete and exclusive domination in Britain, and the considerable limitations in the international flow of economic ideas as far as Britain is concerned are more or less closely

bound up with what Professor Pigou has called "the Marshallian dictatorship." I certainly do not wish to suggest anything in the nature of a black-and-white contrast between the generous cosmopolitanism of Jevons' Preface and the tendency to insularity or exclusiveness of the Marshallian school of thought. In fact, a wide and cosmopolitan exploration of French and German writings in his first few formative years as an economist, during which he had found his way to the works of Cournot and von Thünen, then scarcely known in Britain, had of course contributed centrally and essentially to Marshall's *Principles*. In fact, it was mainly through the *Principles* that Cournot's and Thünen's ideas became a generally recognized part of economic doctrine. But the Marshallian school of thought thereafter proceeded in a somewhat insular independence of the work of Walras, Pareto, Wicksell, and the Austrians, treating Cournot and Thünen as something of a once-and-for-all import which is was hardly necessary to follow up once the *Principles* had been launched.

The explanation of this attitude would seem to be somewhat as follows. The economic ideas which will readily flow internationally are the sort of precise abstract mathematical or quasi-mathematical formulae which Marshall considered to be a very small part of economics proper and in isolation apt to be misleading. As Keynes put it, "Marshall arrived very early at the point of view that the bare bones of economic theory are not worth much in themselves and do not carry one far in the direction of useful, practical, conclusions." The theoretical skeleton had to be covered, clothed, and brought to life by a complement of historical and descriptive economics which was inevitably subject to a considerable national relativism, particularly if the ultimate objective—the guidance of policy—was kept in view. Moreover, Marshall considered that a more or less adequate abstract analytical "organon," as he called it, had been created and, as Mr. Harrod has said, "his programme of work for them [his pupils] was to study the workings of the economic system in all their rich and varied detail with the aid of principle; it was a programme for the development of applied economics." (*The New Economics*, edited by S. Harris, page 65.) Theoretical innovations, imported or otherwise, were rather a waste of time; it was all in Marshall.

Moreover, Marshall wanted a system of economic principles which would obtain and hold the interest of the statesmen, civil servant, banker, and industrialist, expressed in a language they could understand and invoking familiar British names or authorities. His emphasis on the continuity of the national tradition in economics obviously had much to do with this ambition. An architect might in fact be basing his

plans on the latest revolutionary continental principles of construction, but in selling an architectural design to the Bank of England, at least till fairly recently, he would have had a much better chance of success if the novel constructional principles employed were concealed behind a homely, familiar façade in the style we know in Britain "as Bankers' Georgian" (in America, "Bankers' Colonial") than if exposed in some stark unfamiliar un-British construction in the style of the Bauhaus, or Corbusier. Walrasian and Paretian importations, with their mathematics and their foreign terminology of "ophelimities" and "technical coefficients," would simply have frightened off those who Marshall rightly or wrongly regarded as the prospective readers of his *Principles* and of the new *Economic Journal.*

It seems that it is on some such lines as these that the case for the insularity of the Marshallian school of thought would have to be made out. I would be delighted if someone with more understanding of that case than I have were to make it out more effectively.

IV

It can hardly be expected that a summary of conclusions will yield any very firm, precise, or novel points. However, we can see from our survey that just as, by and large, there will be more international exchange the more active national economies are, so the flow of ideas internationally became more active when in each of the national centers more new ideas were forthcoming. Again, just as graded or precisely standardized wheat will usually be traded internationally rather than loaves of bread, so the international exchange of ideas came about mainly in formulae of pure analysis easily susceptible to precisely standardized mathematical expression. We can see also that the development of economics as an academic discipline, carried on increasingly and mainly by university teachers, led, on the whole and with considerable and sometimes glaring exceptions, to the recognition of standards of scholarly presentation requiring a more extensive and systematic acquaintance with serious new work, whatever its language or country of origin. On the other hand, the emergence of powerful local academic schools, representing monolithic doctrinal systems, with their tenaciously held philosophical or methodological presuppositions, terminological dogmas and war cries, held up the flow of ideas between different centers, or at any rate prevented their mutual permeation, modification, and agreed unification. Finally, much depended on the personal intellectual tastes and psychology of the main leaders.

The problem today is very different. With the vastly increased number of translations and of widely circulating specialist journals,

including international journals, and with the increasingly mathematical character of advanced economic analysis, it seems, on the whole, very unlikely that good new ideas, whenever or wherever they do arise, will not have a reasonably fair chance of being heard and of making their way. I am speaking, of course, simply of the world this side of the Iron and Bamboo Curtains. The problem today is probably not whether there has just been published a *Recherches* of Cournot or an *Interest and Prices* of Wicksell, the vast significance of which will eventually come to be generally recognized and followed up by about the time of the 1990 meeting of this Association. The problem is probably not that there are Cournots among us whom we are failing to recognize but rather that Cournots are just not coming into existence at all. The question is whether by one of those typical paradoxes of improved organization and larger scale, which in the moral and social cosmos so often empty out babies with bath water, the very expansions and refinements of intellectual machinery which have removed former lags and impediments in the flow of ideas have not at the same time removed one of the former sources of original new ideas. In the period we reviewed, much that was new and vital came first from those whose main interests, or from those some of whose main interests, were outside economics (like Cournot and Dupuit and even to a different and lesser extent like Jevons and J. S. Mill), from intellectual frontier types, or from slightly crankish outsiders (like Hobson and Johannsen). Vastly increased specialization and the disappearance of independent incomes has to a considerable extent removed this kind of thinker, who was so fertile in the period we have been considering. Economists are now part, even often from their undergraduate years, of large, organized, internationally-linked academic machines, with their subjects closely organized and defined and their questions and categories ready formulated, and the problem that arises is whether at the same time a main source of stimulus to intellectual advance, even though it was one which almost inevitably operated often only after long time lags, may have disappeared. It is quite impossible to assess the answer to this sort of question of hypothetical opportunity cost, but perhaps the question is worth asking all the same. Adam Smith, though extolling the productivity of the division of labor in manufacturing industry, was very apprehensive as to some of its applications and results in other spheres.

Much, inevitably, has been said about Marshall in this paper; so let us conclude with a typical quotation from him, which bears on our point and on much else besides and which radiates wisdom like the expanding ripples from a stone dropped in a still pool: "The widening range of standardised methods [in science] tends generally to increase

the dependence of the creative mind on large capitalistic aid in obtaining scope for its activities. . . . The fact that Aristotle, Newton and Cuvier would have much to learn, if they should meet a mediocre student of modern science on his arrival in Hades, does not tell entirely on the side of the present age." (*Industry and Trade*, pages 242-243.)

THE ROLE OF THE GERMAN HISTORICAL SCHOOL IN AMERICAN ECONOMIC THOUGHT

By JOSEPH DORFMAN
Columbia University

Just as American economic thought has affected developments abroad, so have foreign streams left an impress on the American scene. The British stream of ideas has been by far the dominant one. But then the American cultural heritage is predominantly British. This is especially true of the political and economic institutions—the basic conditioning forces. To unfold the highly complicated story of the naturalization of British economic thought on American soil would require much more than one session. Let me restrict my address to a more manageable foreign stream. Let me take the German Historical School which was especially influential in the seventies and eighties. In the broad flow of history, this movement was a contributory force to the renaissance in American intellectual life that accompanied America's great industrial revolution in the post-Civil War era.

As they envisaged the promise of America's industrialization, enlightened men were anxious to avoid the ills that disfigured England's factory and machine age and threatened the Anglo-American tradition of liberty. In an effort to cope with the pressing economic issues of the new era, progressive-minded economists began to question the adequacy of traditional, classical economic theory which dominated America in a vulgarized form. They sought ways not only to explain but also to fructify the economy and build up social wealth. They were concerned, not only with analysis, but—in an incipient way of course—with social engineering.

Technically the origins of the German Historical School go back at least to the middle of the nineteenth century, but it received a strong impetus from the intellectual revolution symbolized by the name of Darwin and the effort in all fields to assimilate the doctrine of evolution. So far as the Anglo-American world is concerned, it was a movement to do for economics what Sir Henry Maine did for English jurisprudence in correcting the overanalytic emphasis of the dominant Austinian School by an infusion of historical and comparative methods. This was not the old-fashioned history, hardly distinguishable from belles-lettres but the new history that was concerned with detailed, objective inquiry. It was in this atmosphere that the German Historical School makes its appearance in America.

We may begin with a formal event. In 1877, the Trustees of Columbia appointed the German-trained Richmond Mayo-Smith to develop economics on an inductive basis. They hoped he would follow in the footsteps of Continental European pioneers who "brought together . . . the . . . information . . . gathered by the statistical bureaus of the several governments, and have sought to infer . . . the system most favorable to industrial development, to growth in national wealth and to the fairest and most equal distribution of the rewards of labor."[1] Here was the formal acceptance of the German Historical School in the academic world.

The school—or more properly, members of the school—had come to the attention of Americans in various ways. There were, of course, the American students who had studied in Germany. Even before that movement took on large proportions, there was knowledge of the school through English and French periodicals which were widely read in the United States. There was also the deep interest of some American economists in statistics and therefore in the techniques developed by the Germans. For example, as early as 1863, Samuel B. Ruggles, as the official American delegate to the International Statistical Congress at Berlin, expressed his conviction that "abstract theories and historical traditions doubtless have their use and their proper place, but statistics are the very eyes of the statesman, enabling him to survey and scan with clear but comprehensive vision the whole structure and economy of the body politic." A few years later, at the next Congress, Ruggles met and was deeply impressed by Ernst Engel, head of the Royal Statistical Bureau of Prussia and one of the most famous economists of Europe. His Bureau was unique in that it included a "seminary" to train university graduates who qualified for admission to the higher branches of the civil service. In this way, governmental offices, like the Statistical Bureau itself, would become laboratories of political science. Engel was deeply interested in social problems. He visited England to study labor conditions in the most advanced industrial nation. He was one of the promoters of the organization of German economists in 1872—the Union for Social Politics—that apparently first gave prominence abroad to the Historical School. The organization espoused social reform along English precedents and was soon confronted by hostile critics, who nicknamed the members *Katheder-Sozialisten* (Socialists of the Chair). Rumors soon circulated abroad that the organization advocated socialism, supported breaking of labor contracts, and favored strikes.

The picture was obscured abroad by the general lack of knowledge of German economics. To overcome this difficulty in England, the

[1] Cited in Joseph Dorfman, "The Department of Economics," in *A History of the Faculty of Political Science of Columbia University* (New York, 1955), pp. 170-171.

Fortnightly Review published an article in 1873, written by Professor Gustav Cohn, on the state of German economics. Cohn pointed out that the Union was influenced by the widespread revolt in the learned community against the highly abstract reasoning of the eighteenth century with its emphasis on natural rights, state of nature, laws of nature. They insisted on the need to understand "the facts which preceded the modern state of society" before any reasonable conclusions concerning the future could be drawn. These economists were, he continued, affected by the success of the inductive method in the natural sciences and the progress of a philosophy which asserted the authority of society and the organic character of the state against the workings of extreme laissez faire.

Two years later, the same magazine published a review article that set off a controversy in the United States over the German Historical School. Wilhelm Roscher, the patriarch of the school, had just published *The History of German Political Economy.* Professor T. E. Cliffe Leslie of Queen's College, Belfast, in the review defended the school against the charge of being socialistic. In this essay he said:

> Man, in the eyes of the historical or realistic school, is not merely an "exchanging animal" . . . with a single unvarying interest, removed from all the real conditions of time and place—a personification of an abstraction; he is the actual . . human being . . . history and surrounding circumstances have made him, with all his wants, passions, and infirmities.

He pointed out the wide range of the publications by members of the German Historical School and insisted that:

> A great diversity of opinion is to be found among the economists of this school . . . ; some being conservative and others liberal in their politics; but no revolutionary or socialist schemes have emanated from its most advanced Liberal rank. Their principal practical aims would excite little terror in England. Some legislation after the model of the English Factory Laws, some system of arbitration for the adjustment of disputes about wages, and the legalization of trade unions under certain conditions, are the main points in their practical program.

Leslie's essay attracted the attention of the *Commercial & Financial Chronicle* of New York. In a eulogistic editorial it declared that the new German school treated the forces that caused a nation to grow in wealth. Interest in the school was stimulated by another eulogy which appeared at the same time in a French organ, *Revue des Deux Mondes.* The article was written by the eminent Belgian economist, Émile de Laveleye. He fanned the flames of controversy by contending that the erroneous belief in natural laws strengthened the opposition to bimetallism and protectionism, both of which, he argued, were essential to business prosperity.

This brought the *Nation* into the arena, a journal which exercised the greatest influence on respectable opinion. The editor, E. L. Godkin, was a firm adherent to the creed of free trade and the gold standard. He wrote an editorial asserting that the new group of German economists

were erudite university teachers with little public experience and long accustomed to accepting militarism and bureaucracy. In fact, they were socialists. Immediately the *Nation* received protests from several of its prominent readers.

One defender of the school was W. F. Allen, of the University of Wisconsin, who had studied in Germany. He was an orthodox Ricardian in his foundations. He strongly opposed, however, the extreme laissez faire of the dominant economics. It is all very well, he said, to point out the socialistic tendencies and the disastrous effect of public poor relief, for example, but after all was it proper for the state to "suffer its citizens to die of starvation in open day"? ("Fawcett's Essays," in the *Nation,* September 25, 1872, page 204.) He was, therefore, in sympathy with a school which he felt accepted the foundation laid by Adam Smith but built a new structure on it.

The *Nation* conceded that the German economists were not socialists but insisted that they had been blinded by resentment against the incidental, wild speculation of the prosperous era, which unification had brought to Germany.

The following year the controversy was intensified by the attack of the French economist, Maurice Block, which appeared in translation in the *Penn Monthly.* In the name of the "scientific school," he denounced the German Historical School and Leslie as "empirics" seeking to substitute sentiment for principle and holding that "the state . . . should conduct everything, direct everything, decide everything." Leslie asked the *Penn Monthly* to reprint a small extract from his article, "On the Philosophical Method of Political Economy," which would show that far from being an opponent of the philosophical spirit, as Block had claimed, his object had been to explain what the philosophical method ought to be. The journal decided to reprint the essay in full, because "it . . . represents a real advance in the development of economic science."

In 1878, with the aid of Allen, John J. Lalor, a sound money and free trade journalist, brought out the English translation of Roscher's famous *Principles.* This was immediately attacked by William Graham Sumner, who presented the view of dominant orthodoxy. Sumner stated that the work was distinguished by its pervasive faith in the state. History and statistics could not be merged with "dogmatic economics" but were separate disciplines.

Nevertheless, interest in the school continued to grow. John Kells Ingram, of Trinity College, Dublin, gave an important address before the British Association for the Advancement of Science in 1878. Ingram condemned the extremely abstract method of current English economics and declared that the study of the economic phenomena of society

should, in accordance with the historical method, be systematically combined with that of the other aspects of social existence. He pointed out that the essentials of the method were presented by the Secretary of the Union for Social Politics. Adolf Held, a student of Engel, had published elaborate inductive studies in taxation. He warned against too abstract theorizing on tax incidence and against overestimating the income tax as the sole means of reaching the entire taxable capacity. At the moment, Held was attempting to meet the challenge of socialism by supporting an advanced program of social security that culminated in Bismarck's legislation of sickness, accident, invalidity, and old age insurance. Ingram presented Held's standpoint in his own words:

1. The new school . . . opposes . . . the view . . . that the production and acquisition of wealth by individuals is the single . . object of human life; wealth, it regards as a means used by Humanity in its struggle towards moral ideas of life, and for the furtherance of universal culture

2. It . . . seeks to understand present economic phenomena through the study of their historical development, and to ascertain them as accurately as possible through statistical investigations. It uses the knowledge of the nature of man's intellect and will for the rational explanation of economic facts, but does not construct those facts themselves out of one sided assumptions respecting the nature of man.

3. It . . . recognizes the right of the state to positive intervention in the economic relations of the community, for the support of the weak and the strengthening of public spirit. As the Political Economy of the last century applied itself chiefly to the liberation of the economic forces from antiquated and useless restrictions, so the new school specially meets the acknowledged need of new social arrangements, the need of social reform in opposition to social revolution on the one hand and to rigid *laissez-faire* on the other.

4. It takes up, therefore, a less isolated position in relation to the other Moral and Political Sciences

In a quiet way the school had already struck root. Already in 1875, Colonel Carroll D. Wright, chief of the Massachusetts Bureau of Statistics of Labor, had introduced Engel's law of consumption. He drew upon Engel's studies to make a comparison of the condition of the workmen in Massachusetts with that in other states and foreign countries. Wright went a step beyond Engel and concluded also "that the higher the income . . . the greater the saving, absolutely and proportionately." Thanks to Wright, the study of family budgets was developed which, whether in the form of "Engel tables" or "Engel curves" has become so pivotal in economic analysis in our day. Engel also influenced Wright's fundamental work on the structure for a price index which has provided the statistical substance for many far-reaching decisions, such as adjustment of wages to cost of living. Inspired by Engel's success in training statisticians, Wright successfully promoted among American colleges the establishment of courses in statistics.

The German influences were summed up by Wright himself. The new school, he exclaimed, "bids fair to include on its roll of pupils the men in all civilized lands who seek by legitimate means, and without revolution, the amelioration of unfavorable industrial and social relations." *(The Relation of Political Economy to the Labor Question*

[1882], page 13.) The rigidly orthodox promptly castigated Wright as being infected by the socialists of the chair who stress moral forces and ignore the primitive and more elementary force of self-interest. Wright, however, continued to plead for social reform, in terms of the idiom of the Historical School. Thus, while the United States Commissioner of Labor in 1893, he described the German social legislation as a brave attempt to reduce economic insecurity.

Equally receptive to the school was a scholar who was to become the country's foremost economist and statistician, General Francis A. Walker. He insisted that the classical economics, as formulated by John Elliot Cairnes, furnished the skeleton foundation for sound economics, but he questioned the wage-fund doctrine and supported international bimetallism. Walker castigated the reigning orthodox economics for its extreme conservatism. He observed their neglect of historical methods, and their overemphasis upon an a priori method which achieved a simplicity in classification to which the subject matter was not susceptible. These factors, he said, in 1879 had cost the science of economics public regard, especially among the laboring classes. As a remedy for this, the Historical School, it seemed to him, offered the greatest promise. "The economists of Germany, Italy, Belgium, and France," he wrote, "are doing the work which Adam Smith began, in his spirit, but with larger opportunities and a wider and ever widening view."[2]

The movement reached a high pitch in the eighties, especially under the impact of English writings, that opened up the field of economic history. Indicative of the temper of the times was the fact that the article on "Political Economy," in the ninth edition of the *Encyclopaedia Brittanica* (1885), was prepared by Ingram; and the *Encyclopaedia,* of course, was an authority here as well as in England. The essay was quickly reprinted here for use in college classes, largely through the efforts of F. W. Taussig.

The Historical School was scoring, again because an ever increasing number of college graduates were going to Germany for advanced work in the seventies and eighties. Germany had long been known as the land of scholarship, a land where, it was said, professors achieved a "degree of perfection . . . that astonishes the world." (F. W. Taussig, "College Graduates in Germany," in the *Nation,* April 2, 1885, page 275.) And it was pointed out in 1876 by Charles F. Dunbar, of Harvard, that the lead in economics had now passed from England and France to Germany.

The young men who went to Germany were imbued with a lively

[2] Walker, "The Present Standing of Political Economy," 1879, reprinted in Walker, *Discussions in Economics and Statistics,* Vol I, edited by D R Dewey (New York, 1899), p. 318.

interest in statistics. A number who studied with Engel and his assistant, August Meitzen, at the Royal Statistical Bureau, achieved considerable prominence. Henry Carter Adams became the first statistician of the Interstate Commerce Commission and devised its pivotal accounting system which served as a model for the regulation of public utilities here and throughout the world. Roland P. Falkner was the first man to hold a leading American university post devoted exclusively to statistics, at the Wharton School of the University of Pennsylvania. He prepared the translation of Meitzen's *History, Theory, and Technique of Statistics*. His work on the famous Aldrich Report of 1893, *Wholesale Prices, Wages and Transportation,* was one of the landmarks in statistical investigation. Richmond Mayo-Smith became the outstanding teacher in statistics, and turned out such students as Walter F. Willcox and the inventor of the electrical tabulating machine, Herman Hollerith.

Another area which left a definite impress on American students was the systematic treatment of public finance or, as the Germans called it, the "Science of Finance," a subject which the English had neglected as comparatively unimportant. Interestingly, in line with this emphasis, the American pioneers in the field followed a German precedent in substituting the term economics for political economy, as the more comprehensive term. Political economy was restricted to private finance, or the domain of voluntary association. The term public finance covered the "wants of the state and the means by which they are supplied." Political economy and the science of finance became branches of economics. (See Joseph Dorfman, "Henry Carter Adams: Harmonizer of Liberty and Reform," introductory essay in Adams, *Relation of the State to Industrial Action and Economics and Jurisprudence* [New York, 1954], page 13.)

Students were also impressed by the scope of national economy covered in the massive works of such leaders as Roscher and Adolph Wagner. For example, comprehensive instruction was given, not only in principles, but also in agriculture (including forestry), transportation, commerce, manufactures, and finance. It was under this impact that Adams urged the need for a course on "American Technics" which would comprise the contributions of agriculture, manufacturing, and transportation.

To clarify the nature of the influence of the German Historical School, let me discuss specifically five German-trained economists who were the leading promoters and the first officers (along with Walker) of that landmark in the development of economic thought in America, the American Economic Association.

J. B. Clark (in "Unrecognized Forces in Political Economy," the

New Englander, October, 1877, page 712) warned that the assumed man of orthodoxy "is too mechanical and too selfish to correspond with the reality; he is actuated altogether too little by higher psychological forces."

E. J. James was more positive. He attracted attention through his contributions to the authoritative *Cyclopaedia of Political Science, Political Economy, and of the Political History of the United States* (1883-84). His articles ranged from the "History of Political Economy" and "Finance" to "Banks of Issue" and "Factory Laws." In the spirit of his German training, he declared that factory legislation could be justified, not only as protection for the helpless, but as an essential movement in the interest of society. To quote: "A state has other and nobler ends to follow than the accumulation of mere material wealth.... Moderate wealth and happy homes are better than a degraded proletary and ability to underbid all competitors in the industrial world."

Richard T. Ely was the most provocative of the group. He had not only studied in Germany but found it desirable to spend there a good part of each of the three years, 1911-13, in order to complete his most substantial book, *Property and Contract*. On his return in 1880 from his first trip to Germany he found academic openings scarce. Forced "to wander about the streets of New York . . . in a most wretched desperate state," he vowed to "use every opportunity to benefit those who suffer."[3] After a year and a half he obtained a foothold at Johns Hopkins. To aid in devising the best methods of carrying out proposed reforms and executing the laws, he lectured on the "Principles and Practices of Administration with Special Reference to Civil Service Problems and Municipal Reform." City planning, the mother of modern planning, likewise owes much to Ely. He was deeply impressed with the efficient administration of German cities by a permanent civil service which included the highest officials. A considerable advantage of a civil service, he wrote in 1880, was the permanence and steadiness of policy. Plans could be laid for a number of years and carried out gradually as a city could afford to execute them.

While still fresh at Johns Hopkins, he published widely read studies on the "new political economy." He granted that the older political economy had considerable merit. It separated wealth from the other social phenomena for special study. It showed the impossibility of understanding society without investigating the processes of the production and distribution of goods. In serving to pull down outworn institutions, it answered satisfactorily the needs of the latter part of the eighteenth century and the early part of the nineteenth century, but

[3] Ely to Labadie, August 14, 1885, in "The Ely-Labadie Letters," edited by Sidney Fine. *Michigan History*, March, 1952, p. 17.

like the French Revolution it was negative. Not least among the merits of the new view, Ely said, was that it gave a more concrete interpretation of economic history, by attempting to understand past doctrines in the light of their environment. He especially commended Wagner for his statement of the three ethical principles underlying economic policy. The first was the principle of individualism. This was modified by the social principle which acted through the state. Finally, there was the "caritative" principle—the principle of brotherly love expressed in voluntary action on behalf of others. Charity was only one form. The principle softened the rigors of life in ways that the social principle could not, for it was not obliged to operate according to fixed rules. Ely also noted Wagner's program for comprehensive social security that would eventually include protection against unemployment during hard times. Ely's emphasis, as early as 1882, on the acceptance of German social legislation, was prophetic. "It behooves . . . Americans to follow diligently the course of these experiments," he stated, "for we may be sure the same social problems which now vex Germany, will one day confront us." ("Bismarck's Plan for Insuring German Laborers," in the *International Review*, May, 1882, page 526.) To this end, he, along with Henry Farnam, later promoted the American Association for Labor Legislation.

Ely also pointed out that government regulation of industry provided the means of effectively applying the inductive method, for the legislation necessitated the systematic gathering and classification of data. He got John R. Commons and other students to prepare the famous *History of Labour in the United States*. In his widely used *Introduction to Political Economy*, Ely not only presented Engel's law, but called attention to Engel's basic objective "that it might be possible by a careful study of a sufficient number of family budgets for a period of years to construct a sort of *social signal service*"; in other words, "that changes in total expenditures and in expenditures for various items in a sufficient number of typical families could enable one to predict the coming of industrial storms."

Henry Carter Adams, though he found the Germany of Bismarck's day an example of efficiency and enlightened reform, warned against the dangers to liberty implicit in indiscriminate state intervention. He admired the German methods of study and their skill at systematization, but he was disturbed by their worship of the state. This lay at the heart of his warning, in speaking of German university training. "It is not possible," said Adams, "for an instructor whose lectures are worth the hearing to separate himself from the peculiar influence of his time and immediate environment, and in Germany especially do the lectures one hears upon political sciences reflect the bias of German local and

national policy." ("Political Science in German Universities," in the *Michigan Alumnus,* January, 1899, pages 137-138.) On the other hand, Adams was also disturbed by the workings of unrestrained private enterprise in America, which in another century, he felt, would contradict the theory of freedom and destroy the government. "From this dilemma must arise," he said, "an American Political Economy—an Economy which is to be legal rather than industrial in its character." ("The Position of Socialism in the Historical Development of Political Economy," in *Penn Monthly,* April, 1879, page 294.) In this he was deeply impressed, as he wrote in 1878, with Wagner's view that the tendency in economic study was towards jurisprudence.

Adams noted the need for forest conservation, and he pointed out that corporations could not undertake such a task because the fruits of the investment were too remote. In the famous monograph, *Relation of the State to Industrial Action,* he declared that there were two important functions that the government could perform in the industrial area. First, the state could raise the ethical plane of competition. For example, factory legislation need not curtail competition, but it could remove serious abuses in the factory without eliminating the benefits of individual action. Second, the state may realize for the public good the benefits of monopoly. For this purpose, Adams developed the principle of "increasing returns" to cover industries which lend themselves to public control; for example, the railroads.

Government control, Adams argued, would not necessarily lead to corruption. Corruption was due to the lack of correlation between the public and private functions. The inducements offered in the two varied widely. Extension of the state's functions, manned by a well-paid civil service, would restore the harmony between state and private service, for it would bring social distinction, the chance to exercise one's talents, and the pleasure of filling well a responsible position.

Factory legislation and monopoly regulation, however, did not touch the problem of the rights and duties under which work is done. This brought Adams, in 1886, to the need of building up a common law of labor relations, through collective bargaining.

Explicitly building on Held, Adams contended that in the scheme of petty industry, the regime of tools, the ordinary rights of personal freedom, secured to men an enjoyment of the fruits of their labor. In the great industries of today, however, the laborer was dependent upon the owner of machines, of materials, and of places for the opportunity to work. It followed that laborers must unite or they would surely get the worst of any bargain. Underlying labor's demands was the "idea" that the laborers had some right of proprietorship in the industry to which they gave their skill and time. Thus collective bargaining and the labor

contract envisaged a crystallization of a common law of labor rights which was in full harmony with the development of Anglo-Saxon liberty.

Finally, E. R. A. Seligman did much to clarify the objectives of the Historical School. He said, in 1883, that the difference between the orthodox school and the modern German school was not between deductive and historical methods. The exclusive use of either led to absurdities, producing an unreal science or a body of archeological facts. A judicious combination of both was the only permissible procedure. The chief point of difference was that the orthodox had an atomistic, individualistic point of view; the other had a social standpoint. The orthodox posited the universal spirit of self-interest; the other stressed the "multiplicity of motives which cannot be jumbled together in the phrase, 'desire for wealth.'" It emphasized, also, the importance of legal systems and historical causes and the close connection between ethics and economics as sister moral sciences. Seligman felt that only extremists would deny any value to the views of those on the other side. He called attention, however, to the "practical use to which the bald, unqualified, and therefore untrue theories" have been put in late years. For example, the so-called "scientific socialism" of Lassalle and Marx was the "logical conclusion from the premise that labor is the cause of all value, and many of Mr. Henry George's wild fallacies are traceable to an almost superstitious acceptance of the Ricardian law of rent." The state, concluded Seligman, had a duty to interfere where free competition ends disastrously, and "where the powers of state themselves are threatened . . . by corporate monopolies." ("Sidgwick on Political Economy," the *Index*, August 16, 1883, pages 75-76.)

Despite the numerous attacks on it, the "new school" had made its way. In the seventies and eighties, it furnished a rationale for combating the arrogant individualism of the time. Its emphasis on history and statistics was a powerful force in developing these mighty instruments for the expansion of economics. Its impact is epitomized in the statement of principles of the American Economic Association on its formation in 1885:

1. We regard the state as an agency whose positive assistance is one of the indispensable conditions of human progress.
2. We believe that political economy as a science is still in an early stage of its development. While we appreciate the work of former economists, we look not as much to speculation as to the historical and statistical study of actual conditions of economic life, for the satisfactory accomplishment of that development.
3. We hold that the conflict of labor and capital has brought into prominence a vast number of social problems, whose solution requires the united effort, each in its own sphere, of the church, of the state, and of science.
4. In the study of the industrial and commercial policy of governments we take no partisan attitude. We believe in a progressive development of economic conditions, which must be met by a corresponding development of legislative policy.

Having given so much, let us take something away. The statement of principles was in a few years dropped. For a while there occurred an overwhelming emphasis on the doctrine of marginal utility as the key to all economic analysis. Interestingly, the German-trained contingent was the first to welcome Jevons' theory as a part of the new economics (Clark attributed his own version of marginal utility to the inspiration of his German teacher, Karl Knies), but they had hardly intended that economics should be restricted to this doctrine, a development which was accelerated by the popularity of the translations of the nonmathematical, "Austrian" works. The creation of chairs of economic history, sociology, and social ethics tended to remove from economics the issues that had made the Historical School a vital force, especially the concern with the moral problems presented by industrial changes.

We are ready to sum up. From the beginning, the Americans followed the German Historical School in a discriminating fashion. They distinguished between its methods and its political philosophy. The first they adopted with enthusiasm, and made it an enduring feature of American economic thought. They diversified their scientific study. They developed new realms of interest, such as public finance, railroads, agriculture, labor, and the history and significance of technological and legal relations. They kept alive a serious interest in the systematic treatment of "commercial crises." They enriched economics with historical and sociological material. It became difficult henceforth to discuss even the most abstract doctrines without reference to statistics, history, and environment. Yet Americans adapted the attitudes of the German Historical School to their own traditions. For the Germans, the organic character of society was reduced to a question of action by a centralized and almost dictatorial state authority. This is not what organism meant to the Anglo-American mind. The national state was not the only embodiment of society. In the United States, particularly, there was a multitude of state and local authorities. There were, in addition, entities of a social or economic sort that exercised organic functions. In the new doctrine, therefore, as transformed by the Anglo-American mentality, doctrinaire individualism was modified or corrected by the encouragement of the powers and functions of a great many aggregates. This spelled the fundamental distinction in political outlook between the Historical School in its native land and its American heirs.

DISCUSSION

J. M. LETICHE: The papers presented by Professors Hutchison and Dorfman constitute an important event in the history of our discipline, for to my knowledge this is the first appearance of research which has been conducted expressly and systematically on the international flow of economic ideas. It is an appropriate occasion to raise general questions about a great deal rather than particular questions about a little. Why is the international flow of economic ideas a problem? What are the contributions and hypotheses which emerge from this new research? How are they relevant to the economist in the twentieth century? These are the three questions to which I shall direct my attention.

To what Professors Hutchison and Dorfman have said as to why it is a problem, I wish to add here only the following comments. The study of the international flow of economic ideas deserves particular attention for its possible contribution to the future rate of development of our science, both within and across national and linguistic frontiers. Among nations of the noncommunist world, the state of economics in the mid-twentieth century appears to be distressingly fragmentized particularly along national lines. In the communist dominated world, this field adds no support to Soviet claims of discovery. Since the second World War, the United States has become an important exporter of economic ideas, but as yet we know little of the relation between this exportable product and the altered form which it takes in new intellectual and institutional environments. We face the problem of adjustment from the role of a net importer to that of an expanding exporter of basic research. The impact of this adjustment upon our own scientific advance is of great importance. Recent appraisals of our science by Professors Schumpeter and Robbins reveal no strong ground for complacency. Schumpeter asserts that the theory of our time is greatly superior to the theory of 1900 as regards technique. He writes in his recently published *History of Economic Analysis:* "Results are more reliable, proofs are more rigorous. This in itself also means *more* results and more *specialized* results that fit better the endless variety of the configurations of economic reality. At the same time it must be admitted that fundamentally new ideas have been almost wholly absent. We make much more of the ideas which we have inherited from the preceding period and often present them in a new light, but we have added little to them." (Page 1145.)

Robbins in his book, *The Economist in the Twentieth Century* (pages 1-17), notes that in the last fifty years important contributions have been made in the general theory of money and output. He agrees with Schumpeter that development in the applied fields has been remarkable. I think we all recognize, however, that, while our profession has witnessed much advance in the techniques of economic analysis (i.e., in economic history, economic theory, statistics, and economic sociology) and that within limits they have proved their practical usefulness, the deficiencies of our knowledge are

lamentable and must continue to be a source of embarrassment. Research on the nature of the development of economic ideas and their international impact is, therefore, long overdue.

Professor Hutchison has shown that between 1871-74, Jevons, Menger, and Walras reached similar conclusions with respect to marginal utility analysis without, for the most part, reacting to, or being stimulated by, any common cosmopolitan intellectual situation brought about by an active international interchange of ideas about the problem of value or any other economic problem. In effect, they reached their discovery by their own original and mainly nationally independent routes. This discovery represents yet another important case study of advance in analytical economics which revealed inadequate former technique. Many of our intellectual resources would be freed if it were recognized once and for all that the development of our science cannot be explained in deterministic terms or on grounds of the author's "politics" or "what he stands for."

There has been a continuous, though somewhat zigzagged, development in techniques per se. I shall argue in a moment, however, that another branch of growth had different roots, has been more complex and probably more important for the international flow of economic ideas.

Regarding the increase in the international flow of economic ideas which occurred in the 1870's, Professor Hutchison says that it may be traceable to the abstract or mathematical nature of the new ideas on value and to the gradually increasing importance of the academic scholar. These factors were probably important, but I doubt whether economic ideas expressed in nonmathematical terms are less likely to obtain an international hearing than those expressed in mathematical terms. The opposite experience has probably been the case as illustrated by the fact that Adam Smith used not a single mathematical or highly abstract term. Yet English editions and translations of the *Wealth of Nations* appeared in Ireland, the United States, Denmark, Holland, France, Germany, Italy, Spain, and Russia within approximately twenty-five years of its publication.

Professor Hutchison observes that the intellectual ferment, considerable cosmopolitan interchange, and significant development of economic ideas that occurred generally in the early 1890's are to be matched only by the insignificant inflow and development of ideas in England during Marshall's predominance. Hutchison suggests that England's insular independence of the work of Walras, Pareto, Wicksell, and the Austrians was primarily the result of Marshall's emphasis upon "historical and descriptive economics which was inevitably subject to a considerable national relativism," particularly if guidance of policy was kept in view. Hence Marshall emphasized the continuity of the national tradition in economics and relied on familiar British authorities and modes of expression. Certainly these national elements played their role, but I submit for your consideration a more general, complementary hypothesis. Whenever a great synthesis is achieved in economics it results in a reduction of intellectual ferment, of controversy, and of national as well as international flow of economic ideas. When one regards Marshall's superb analytical insight, his wide range of information, and, above all, his strong

sense of proportion and relevance, is it at all surprising that he overpowered the economics profession of his generation? Adam Smith also appears to have either overwhelmed or chloroformed his critics. From the publication of the *Wealth of Nations* in 1776 to the founding of the *Edinburgh Review* in 1803 there was a barren period in the development of our science.

While the importance of a free international flow of economic ideas cannot be overemphasized, the general conclusion that I draw from Professor Hutchison's and Professor Dorfman's research is that during the periods analyzed parallel development of economic thought occurred independently in Britain and the United States with relatively little foreign influence. Professor Hutchison tells us in his book, *A Review of Economic Doctrines—1870-1927* (1953, page 67), that "Ricardo, Mill, Cournot, Thünen, Jones and Roscher, representing the English classical system, mathematical analysis, and the historical approach, gave the background from which Marshall started." Walter Bagehot also had a strong influence. Marshall's insistence upon retaining the proposition that the quantities of the factors of production are not given, but are functions of their rates of remuneration is an important difference between the Marshallian and the Austrian system, and obviously follows the British classical tradition.

In his third volume on *The Economic Mind in American Civilization, 1865-1918*, Professor Dorfman cites ample evidence for the contention that in each new generation the economists of the United States "remained fresh in their approach" and carried the ideas of their predecessors a step forward, "bearing witness to the need of change and adaptation in a dynamic economic order." (Page xii.)

I agree with Professor Dorfman's statement about the influence of the German Historical School on American thought, but, as he has written, men such as Simon Newcomb, a professor of mathematics in the United States Navy and Johns Hopkins University, were greatly influenced by Jevons and even more so by Cournot as well as by the German Historical School. Moreover, Jevons was a man who had won a reputation by the excellence of his work in applied economics. His *Serious Fall in the Value of Gold* and his brilliant *Coal Question* met the most rigorous standards of the antitheoretical school. His statistical methods were superior to those devised by the German Historical School.

Professor Dorfman's citations of the German authors concerning the position of the English classical school on such matters as "Induction vs. Deduction," "man not being merely an exchangeable animal," excessive beliefs as to "natural laws" and harmonies, "universal spirit of self-interest," etc., may have dispelled silly notions held by some American economists. But they are either irrelevant or erroneous as an interpretation of Adam Smith, David Ricardo, Nassau Senior, and John Stuart Mill.

It is questionable whether there was any economics as a professional science in the United States prior to the 1880's and 1890's. Previous to that time even in the oldest American universities economics was taught in departments of philosophy or social science. The basis of scientific development cannot come from abroad. Domestic economists can save years of work by

utilizing foreign developments if they are prepared to understand the foreign contributions and if the environment is sufficiently conducive to carry the science forward. Even within a country, economic theories become obsolete, perhaps more often and more rapidly, because the questions which they were designed to answer are no longer of interest rather than because new techniques are developed or new insights lead to detection of error in their inherent logic. Given the different national objectives and various institutions of different countries, this phenomenon appears to be even more important in the development of economics through the international flow of economic ideas. For example, the reception of neoclassical thought in the United States was dominated by the work of Marshall. Yet Taussig, though influenced by the German Historical School, followed a strong American tradition, emphasizing facts and verification. This admittance of theory with an empirical orientation was an important American contribution to economic thought. I believe that the emphasis upon empirical research was to a great extent an endogenous phenomenon stemming from the historical and institutional needs of the American environment. The early work of W. C. Mitchell and W. I. King and of the National Bureau of Economic Research represented the real foundation of empirical research on business cycles and national income in the United States. Empirical market research is another illustration.

In the twenties the saving-investment formulations came primarily from abroad, as did the output employment analysis in the thirties. Yet in each case some parallel work was going on in virtually all the important national centers of economic research.

Since the later thirties and particularly since the second World War, original contributions have been stemming to an ever greater extent from America. By this time great American economists were working at home, and a large number of younger economists had been trained in an environment where controversy and new ideas were welcome. Research is long overdue on the role that migration of people as compared to ideas and techniques has played in the development of scientific knowledge, as well as in economic progress. In his theory of class circulation, Pareto spoke of the role of abstract reason and stratified thought in the development of science; he maintained that the lack of mobility among classes results in stratification of thought, and conversely (see Vilfredo Pareto, *The Mind and Society*, edited by Arthur Livingston, Vol. III, pages 1419-1432, and Vol. IV, pages 1740-1915). In the thirties we witnessed the migration of probably more than half of the best trained Austrian and German economists to the United States. Others came from Hungary, Poland, Czechoslovakia, etc. They served as a great catalytic agent and added greatly to the American scientific output and to the international flow of economic ideas. Recent work in the theory of games, activity analysis, input-output analysis, and oligopoly is associated with the names of some of our most distinguished economists who came from abroad. There is danger that this factor may be exaggerated, since being foreign, their work stands out; but the fact is that they would not have been able to make their great contributions had the American environment not been receptive to their ideas. Their research has to a large extent

been affected by the experiences and problems of the American profession as well. The result of this interchange can be seen by comparing the quality of their output with that of the few good economists who remained in Germany.

The international flow of economic ideas that deal with general theory or technique per se is for the most part neutral to political boundaries. Those ideas pertaining to more specific "models," based on more particular assumptions, recognize national frames of reference. The latter may be utilized to great advantage if wisely applied to the national environment, but pitfalls will be encountered if they are transplanted indiscriminately. The menace of the "ideological approach" to the international flow of economic ideas (as typified by communism and fascism) rests in the fact that it is largely a pathological phenomenon, based neither on economic technique per se nor on national frames of reference. These three categories require clarification by research with respect to the form and effect of the contemporary international flow of economic ideas.

There is important precedent as well as current relevance for the correspondence of the reception of new ideas and the freedom of the environment into which they flow. To the economist in the twentieth century, the international flow of economic ideas is pertinent for at least the following reasons.

The greater the difference between the national objectives of one country and another the less general is the application of economic principles. This fact raises the problem of developing economic ideas which are or can be made more relevant to the various objectives of other countries in the noncommunist world so that they will contribute to the integration rather than the further diversification of those objectives.

American economic thought does not appear to have much relevance to economists in some European countries; for example, to those of France and Italy, not to mention those of underdeveloped areas. I submit that American economists will have to deal to a greater extent with problems of political economy if they are to obtain a more productive hearing abroad; for otherwise there is danger that our friends will look elsewhere. The premises and objectives of a good deal of American economic thought do not appear to be applicable to the problems of many nations of the free world.

The most significant obstacle to the development and the international flow of economic ideas does not seem to be the problem of the disappearance of "frontier types" coming from other disciplines, as argued by Professors Hutchison and Dorfman. I believe that the past half century has produced economists who in analytical power and originality compare well with any other period in the history of our science. The trouble today is that our science is badly compartmentalized. Our writing has become more aesthetic than communicative. As economic theorists, economic historians, econometricians, etc., we appear to be somewhat insulted if anyone understands us. The difficulty appears to be that collectively we know too much for any one of us to know very much. The progress and the international flow of economic ideas is in the future much more likely to depend upon greater synthesis

and upon the application of new general tools of knowledge within the economics profession rather than upon additions coming from other disciplines.

The United Nations, the exchange of persons program, and our educational foundations have greatly assisted in the international flow of economic ideas. Fundamentally, however, basic research is an individualistic phenomenon. It will continue to progress most rapidly in those national environments where genuine scholarship, with its characteristics of spontaneous curiosity, dispersed accident, and free controversy, can best endure.

GEORGE H. HILDEBRAND: As these two excellent papers both show, the history of economics can be interesting both as history and as economics.

From the standpoint of history, both authors are concerned with the dissemination of certain key ideas in economic thought. They are aware that this problem requires more than the establishment of dated sequences, important as these happen to be. Actually, the task belongs to the realm of cultural anthropology. Essentially it involves the processes of geographic diffusion of strategic conceptions, though not the simple type of diffusion originally suggested by Mr. Grafton Elliot Smith.

There is first the question of determining which economists initially proposed significant new departures in thought, at what times and in what places. This leads naturally to the second step: to what extent were the innovators really innovating and to what extent were they drawing upon earlier and more fragmentary suggestions? As Mr. Hutchison says, for example, Jevons and Menger both advanced their main ideas of marginal utility in 1871, each working in isolation. Walras followed, also independently, in 1873 and 1874. Yet all three had a substantial, if mixed, intellectual inheritance at their disposal. Major items in the bequest were the psychological principle of satiety and the notion that demand was an inverse function of price. The donors were Bentham, Jennings, Cournot, A. Walras, Dupuit, Hermann, and Gossen. Drawing upon Usher's theory of invention, I suggest that Jevons, Menger, and Walras performed the work of creative synthesis, generalizing, unifying, and extending formerly isolated and largely neglected ideas. No doubt they were in some degree inspired by a crisis in technical thought, in which they were driven to reject rather than to defend outworn ideas.

This leads to the next main question: the diffusion and circulation of the innovators' major intellectual productions. Partly this is a matter of the geographic distribution of ideas. Obviously distribution is fostered by travel and study abroad, familiarity with languages, and international dissemination of published materials. Professor Dorfman has aptly illustrated these processes, in his interesting account of the influence of the ideas of the German Historical School upon American economic thought after 1870. However, there is another side to the question, well indicated by Mr. Hutchison. It concerns the barriers rather than the channels to effective distribution of new modes of thought. Partly these barriers have been linguistic. Indeed, the obstacle to the circulation of the main contributions to marginal analysis, with the notable exception of Wicksteed, was unfamiliarity with

mathematics. As Hutchison suggests, the situation has improved somewhat in these respects in more recent times.

Partly also there is a formidable barrier in the tendency of established systems of thought to persist, asserting themselves through such very practical media as dominant schools led by strong personalities in control of academic opportunities. We have heard of self-perpetuating groups in politics and business; this phenomenon is not absent from universities. Schumpeter says that French chairs were long barred to the followers of Walras and German ones to those of Menger. Historicism exerted similar dominance in Germany. Mr. Hutchison refers to the eminence of Marshall's leadership in precluding much inflow of Continental teachings into England after the early nineties. By contrast, a vigorous brand of utility analysis, mainly mathematical, was easily transplanted and readily took hold in Italy, fostered by strong intellects such as Barone and Pantaleoni and relatively unopposed by established academic interests, because there were none. Rather ironically, Italy in recent times has lagged rather markedly in the domain of applied economics, primarily because its valuable tradition of pure theory has long dominated academic research and instruction.

To take still another example, consider the relatively slow penetration of English economics by marginal analysis, despite Jevons' pioneer work. Jevons himself felt in 1879 that the only hope was "to fling aside, once and for ever, the mazy and preposterous assumptions of the Ricardian School. Our English economists," he complained, "have been living in a fool's paradise." Yet it remained for Marshall to carry through this intellectual reformation. He did so in typical English style, preserving what he thought was usable from the past, keeping the form while changing much of the content. Thus the classical real cost doctrine of factor supply survived within the newer context of marginalism, in Marshall's system.

Turning now from history to economics proper, I wish first to suggest a few points raised by Mr. Hutchison's paper. I would agree with him that so far as English economics is concerned, the story after 1870 centers on the slow triumph of marginal analysis, first in value theory and later in factor service pricing and distribution. The conquest of Richardianism by the marginalists involved the ultimate seizure of intellectual territory long isolated from Continental contacts and fresh ideas. Credit for the victory goes to Jevons, Marshall, and Wicksteed. Partly the triumph was a revolution from within, wrought by Jevons' own originality of thought. Partly also the victory was gained by the infusion of new ideas from abroad—ideas that Marshall and Wicksteed absorbed and reworked in their respective fashions.

However, I think there was also another influence at work, indigenous to the British Isles. I refer to the theory of wages, which by the end of the sixties represented a genuine crisis in thought. As a result of the onslaughts of Longe and Thornton, the wages-fund theory was now in disrepute, though the odium was somewhat undeserved. The subsistence theory had patently failed to fit the facts of falling urban birth rates and rising real wages. Trade-unionism was growing stronger, winning intellectual support for its claims

to be able to raise general living standards and to redistribute income. To these claims the older theories had no obvious answer.

The reason was that the older doctrines lacked the tools of partial equilibrium analysis; hence an adequate conception of a derived demand function for labor. Though in its crude way, as Schumpeter says, the wages-fund theory was correct in pointing to over-all, short-run limits to raising living standards by simple redistribution of the social product, its reasoning carried no conviction for those partial cases in which union wage raising actually went on and still largely goes on.

The renovation of wage theory began with the work of Fleeming Jenkin, an engineer by profession. In 1870, Jenkin introduced the idea of a negatively sloped demand function for labor services—a concept redolent with skeptical implications regarding the ameliorative claims of unionism. The theoretical possibilities were not lost by Marshall, who went on to work out the principle of elasticity of derived demand. However, Jenkin himself suggested a kind of indeterminacy for the wage bargain, an idea that was taken up and developed in the eighties by Jevons and Edgeworth. Edgeworth in particular was thus led to his famous theory of bilateral exchange. By the middle of the nineties, the principle of marginal productivity had been worked out, in various formulations, by Wicksteed, Wicksell, and Barone. Clearly this history is complex. Yet it seems a safe inference that the crisis of wage theory in England in the sixties had much to do with the revolution in distributive theory that occurred in that country in the three decades that followed.

Turning to a radically different kind of theory—that of the German Historical School—Professor Dorfman has given us a most interesting account of its influence upon American thinking. As he shows, that influence had its constructive side. It was responsible for the introduction of statistics into academic training, and it fostered interest in the accumulation of quantitative data. So were laid the foundations for modern theoretical and applied work of the highest importance. Moreover, the Germans did much to develop the art of public administration. They were, of course, keenly interested in state intervention and control, where again they influenced American thought. There are legitimate differences of view as to how beneficial *in toto* these doctrines of state intervention have actually turned out to be. But there is no doubt that they did help indirectly to temper the harsh and extreme conception of individualism that was hitherto prevalent in American life and thought.

Yet, so far as the German influence is concerned, there is another side to the coin. Inspired by the Hegelian tradition, the earlier Germans such as Roscher, Knies, and Hildebrand attacked the generalizing qualities of pure theory and sought to substitute in its stead various philosophies of history, apparently wholly unaware that the philosophy of history is another type of generalization from natural law premises. The result was intellectual confusion and little else. But the reaction in Germany was not even a return to classical theory, save for the Marxian sect; far less was it a reformulation of classical ideas along more modern lines. Rather, there emerged the pragmatic relativism and antitheoretical bias that typified the methodological futilities of Schmoller and his circle.

Certainly there was nothing either wrong or even unique in that group's emphasis upon the collection of facts. But to paraphrase Marshall, facts themselves teach nothing. They must be related to theory. It was here that the German school failed. It had seen the possibilities of state intervention. Through its quasi-official standing it greatly developed the arts of public finance and administration. Yet its methodological narrowness seems to have prevented it from ever regarding state undertakings other than as problems of organization. The school showed no awareness of the elementary distinction between economy and waste, whatever the purposes of state action. Having rejected traditional theory as obsolete natural law doctrine, with allegedly hedonistic foundations and implications for policy that supposedly were uniquely laisser faire, the group could offer no rational economic criteria for guiding the choice between the things government could efficiently do and those it could not. In its view the state was omnicompetent. Perhaps there is, then, some connection between this kind of teaching and the popularity of crude ideas of physical planning in more recent times.

One last point: I wish that Professor Dorfman had decided to include Thorstein Veblen in his discussion, for I would have been interested in his assessment of Veblen's relation to German historicism. Concededly, Veblen was not a direct product of German teaching. Moreover, as Mr. A. W. Coats points out in the December, 1954, issue of the *Journal of Political Economy*, Veblen severely criticized the Germans for their preoccupation with facts and historical narratives; hence their lack of "a theory of anything" or of "a consistent body of knowledge." Yet I think Veblen shared much in common with the Germans, in the character of his destructive attack upon pure theory, old and new, and in the relativism of his theory of knowledge. That he was the most influential American exponent of these views seems to me beyond doubt. If so, he could be considered part of the German tradition as it developed in American economics.

Regarding the history of economic thought, an encouraging renaissance is under way. These two papers are valuable contributions to its advancement.

William Jaffé: The character of an economy, to which Professor Bladen has alluded, depends in a certain measure upon the character of economists. Not that economists can make any serious claim to shaping the economy in any significant degree, but simply because what is regarded as the character of an economy consists of attributes selected and delineated by economists. Hence our general conception of any economy is bound to be influenced by the character of the economists describing or analyzing it. When economists are swayed by chauvinistic and nationalistic passions, the progress of our science is inevitably affected.

This makes it all the more interesting to reflect upon the personal attitudes revealed in the private correspondence of the economists of the period covered by Professor Hutchison's paper. From the Walras correspondence preserved mainly at Lausanne and Lyons we learn much about the character not only of Léon Walras but also of his most distinguished contemporaries. Their per-

sonal passions and prejudices had much to do with the sluggishness with which economic ideas moved across international and linguistic frontiers.

Did anyone, for example, discourage Edgeworth from presenting Walras' theories before the English public? The evidence is none too clear. Walras wrote to Foxwell on March 13, 1889, saying that he hoped that his theorem of maximum utility of new capital goods, as it then appeared in the corrected proofs of the second edition of the *Eléments*, would be found worthy of being offered to competent English readers. Foxwell informed Walras on March 15 that he had sent these proofs to Edgeworth and that Edgeworth was editing and translating the theorem for insertion in the next number of the *Journal of the Royal Statistical Society*. Edgeworth, however, soon abandoned the project, for as he explained it to Walras in a letter dated March 19, he had encountered technical difficulties in understanding the theorem (see my article in the *Journal of Political Economy*, April, 1935, page 203, and my Translator's Note [3] of Lesson 27 of Walras' *Elements of Pure Economics*). He added, and this is the significant point for our present purpose: "***with whom I have spoken and myself wish you to feel that we have spared no pains in this matter. I have, in addition to the regret which he feels at not being able to put the paper before the British, the feeling of remorse. . . ." Where I have put ***, the original letter shows a piece of illegible overwriting, the only example of this sort of illegibility I can find in Edgeworth's letters to Walras. It looks a little like "Prof.," and it was translated in Aline Walras' copies as "Le professeur." The "professor" might have been Foxwell, who was then a member, along with Edgeworth, of the Council of the Royal Statistical Society; but perhaps it was Marshall. Such a guess is probably not farfetched, particularly in the light of a later event in which Enrico Barone was involved and to which Professor Hutchison calls attention in his paper.

If the English did not display any great alacrity in admitting the contributions of Continental economists to their journals, it must be conceded that these discriminatory sentiments were reciprocated on the other side of the Channel. In fact, such sentiments were quite general in Europe. Did not Walras write to Barone in November, 1895: "One does not get anywhere with the English unless one puts them in their place and refuses to be pushed around by them. . . . I know from experience that having the English against us brings to our side the Americans who are generally well disposed in our favor." Pantaleoni, writing on August 12, 1889, asked Walras confidentially whether he did not agree that Menger was a plagiarist and Böhm-Bawerk a charlatan! Walras replied cautiously on August 17: "I do not think that Menger was altogether fair to Gossen. . . . As for Böhm-Bawerk, it seems to me that in the preface of his last work, he stated explicitly enough that he had borrowed his theory of capital from Jevons [sic! See Preface to *The Positive Theory of Capital*, page xxiii]; but since this theory isn't worth much, I am quite willing to let that pass."

The Iron and Bamboo Curtains of today were preceded three-quarters of a century ago by nationalistic, linguistic, and other curtains—all impeding the

free flow of ideas in the learned world. What, I wonder, would have been the fate of economic theory in this country had Enrico Barone succeeded in his attempt to obtain a chair here? On November 26, 1895, he wrote to Walras and pleaded with him to use his influence with J. B. Clark on his behalf. Had either Columbia or Harvard found a place for Barone at that time, his theoretical work, which, according to Schumpeter, was never properly appreciated in Italy, might have found new scope; and economic theory in America might earlier have been enriched from abroad, as it has been more recently by the teaching of economists who have come to us from many lands.

DEVELOPMENT POLICY IN UNDERDEVELOPED COUNTRIES

THE ROLE OF INDUSTRIALIZATION IN DEVELOPMENT PROGRAMS[1]

By HOLLIS B. CHENERY
Stanford University

Industrialization is the main hope of most poor countries trying to increase their levels of income. It is also the most controversial aspect of the problem of economic development. Attempts to apply general economic principles to this field have usually proven inconclusive. This result has been due to an incomplete theoretical formulation of the problem as well as to inadequate data. In most cases there remains a wide margin of disagreement between the advocates of international specialization and investment in primary production on the one hand and the proponents of "balanced growth" and industrialization on the other.

Most of the participants in this controversy would probably accept the proposition that the primary aim of a developing country is to secure the greatest increase in its income (total or per capita) from its available resources in the long run. The main problem lies in evaluating the amount of scarce resources which will actually be required by alternative types of production. For a number of reasons, the price system, which makes this evaluation fairly accurate in more highly developed economies, is often a rather unreliable guide to the desirability of investment in an underdeveloped economy. Even when corrections have been made for the more obvious defects in prices, such as tariffs and subsidies, there remain two sets of factors which make a partial equilibrium analysis based on existing prices very difficult: (1) the existence of structural disequilibrium in the use of factors of production, with labor commonly underemployed and capital and foreign exchange rationed; and (2) the interconnectedness of productive sectors, as a result of which investment in one may make investment in others more profitable—often called "external economies."[2]

[1] This paper is based on a study of Resource Allocation in Development Programs which has been made possible by a grant from the Stanford Committee for Research in the Social Sciences.

[2] The distinction between these "pecuniary" external economies and the more traditional "technological" external economies has been pointed out by Scitovsky in "Two Concepts of External Economies," *Jour. Pol. Econ.*, April, 1954 Rosenstein-Rodan was among the first to analyze this factor in "Problems of Industrialization of Eastern and South-Eastern Europe," *Econ. Jour.*, 1943, pp. 202-211.

Both of these factors are particularly important in evaluating industrial investments. Less than half of the total use of primary factors takes place directly in the average sector producing an industrial commodity; the remainder is scattered throughout the economy in the sectors producing raw materials, producer services, and other industrial commodities. In contrast, most of the requirements of capital, labor, raw materials, and foreign exchange for agricultural and mineral production and services occur directly in the producing sector. It is therefore possible to take account of the existence of structural disequilibrium fairly well in evaluating nonindustrial investments, but both the existing disequilibrium and the effects of future investment complicate judgments on industrial investment.

The present paper will investigate the influence of these two factors—structural disequilibrium and external economies—on the optimum amount and composition of industrial investment in a development program. Such an analysis can only be made in the context of a general equilibrium model because intersectoral relations are the essence of the problem. The empirical background for the model is taken from an over-all study of the Italian economy[3] and of the development programs for Southern Italy.[4]

The paper consists of three parts. The first summarizes the essential features of the model and the method of application. The second part shows the effect on industrial investment of variation in three key factors reflecting the factor endowments of a given area: the labor supply, the availability of foreign exchange, and the rate of growth. The third part shows the difference between an optimum program which takes into account external economies and one which does not. It also tries to shed some light on the general problem of investment priorities.

I. *A Model of Economic Development*

General Characteristics. In order to throw light on the problems I have just outlined, the analytical model must include the following elements: (1) the use of capital, labor, and purchased materials and services in each type of production; (2) the foreign exchange cost of possible imports; (3) the foreign demand for possible exports; (4) restrictions on the commodity composition of any increase in national income; (5) availability of labor, foreign exchange, investment funds, and other scarce resources.

[3] Preliminary results have been published in H. B Chenery, P. G. Clark, and V. Cao Pinna, *The Structure and Growth of the Italian Economy* (Rome: U. S. Mutual Security Agency, 1953).

[4] Empirical data for the analysis of development programs within the framework of a regional input-output model is being collected by the Input-Output Unit of the Italian government and the Association for the Industrialization of Southern Italy, to which the author is a consultant.

The statistical basis for such an analysis is provided by an input-output table, augmented by studies of consumer demand, export demand, etc. The solution to the problem involves choice between domestic production and imports, between production for the home market and exports, and maximization of output within the given restraints. The analytical technique, therefore, must be the more general one of linear programing, which in this case is a straightforward extension of input-output methods.

The purpose of the investment program is to secure a specified increase in national income with a minimum use of investment funds, subject to limitations on the composition of national income, export demand, labor supply, and foreign exchange availability. In the case of Southern Italy, investment funds are variable through subsidies from the central government, and total investment is therefore variable within limits. In other cases, the maximum growth achievable from a given rate of saving could be estimated by varying the time period of the analysis.

The several restrictions in the model are incorporated in the solution in various ways:

1. The division of national income between consumption and investment is taken as fixed. Consumption is assumed to be a function of per capita income only, as described below. All elements in final demand are therefore determined by the assumed increase in national income.

2. Total investment must equal savings plus the excess of imports over exports, summed over the time period involved (ten years). We are not concerned with the time path of production during the period, however, but only with the flow of goods and services at its end. If necessary, the amount of investment included in final demand may be modified in a successive approximation.

3. The excess of imports over exports must correspond to the required amount of external investment funds determined by the solution. Solutions must be determined for several possible levels of the trade deficit to meet this condition.

4. The price of labor must be such that total demand does not exceed the total supply.

The size of the model used represents a compromise between the need for sufficient detail to illustrate the interdependence actually existing among productive sectors and the necessity to hold down costs of computation. Since the interconnections among the industrial sectors are the most significant, the test model contains nine industrial sectors, two sectors of primary production, and three service sectors. Five export sectors have been distinguished, while imports are possible in ten of the fourteen sectors. This model represents a considerable aggrega-

tion of the original Italian input-output study, which contained sixty sectors, and of the matrix for Southern Italy, which contained twenty-eight sectors.

Elements in the Model. The following paragraphs will indicate the conceptual nature of the various elements in the model. For present purposes, it is sufficient to consider the numerical data as fairly realistic estimates of the parameters involved. The input coefficients and consumption estimates result from extensive statistical investigations, while most of the other relations are based on scantier evidence or (where indicated) on pure hypothesis.

1. *Total Requirements.* As the model is formulated, a specific set of final consumption levels for the several commodity groups is taken as the goal of the investment program. These requirements can in most cases be satisfied from either production or imports. The GNP in the target year will equal the total of these final demands less the import surplus. To simplify the analysis, I assume that capacity in the base year is fully utilized and that in no case will it be efficient to shut down existing production. Present production (net of interindustry use) can then be subtracted from the given final demands to determine the total requirements by sector to be supplied from either increased production (requiring new investment) or imports. These two sets of estimates are shown in Table 3 on page 47.

Final demand consists of government consumption, private consumption, investment, and exports. (The estimates of final demand were made in Italy by the collaborating groups noted above. They were taken as data for the present test, with the exception of some exports, which were allowed to vary as explained below.) The magnitude of investment was based on the estimated sum of domestic savings and the import surplus (as indicated above) while government consumption was projected from past trends; the composition of both was kept unchanged. A more detailed study was made of private consumption. Consumption estimates for some seventy commodity groups were based on population growth and income elasticities related to prospective increases in per capita incomes. They were then aggregated to the present number of sectors.

2. *Production Possibilities.* Each of the commodity groups in the model represents an aggregation of many subgroups. For this test, I have secured average input coefficients through aggregating the intersectoral flows into fourteen groups. I have retained the variation in capital/output ratios within each sector, however, by arranging the subsectors in the order of their capital intensity and assuming that their output will be required in fixed proportions. On this assumption, it will be economical to produce those commodities within each sector

which have low direct capital requirements and import those having higher capital requirements, since the indirect capital use within each major sector is assumed to be the same for all subsectors. (If this assumption is not made, the number of sectors must be increased.)

For the linear programing model, the alternative ways of satisfying the given requirements in sectors where imports are possible consist of mixtures of domestic production and imports. The input requirements for domestic production are given in Table 1, and the capital and labor requirements in Table 2A. Some allowance must be made in using minimum investment as a test of efficiency for the fact that capital goods have different degrees of durability. This was done here in the case of land reclamation and other agricultural construction through reducing the capital requirement by the estimated present value of the capital stock twenty-five years hence. An alternative would be to treat capital consumption as a separate input. The assumed variation in capital coefficients within each sector is largely hypothetical, as are the labor coefficients. The capital coefficients in industry were based on a sample of some seventy-five investment projects which were actually undertaken in the past few years. Imports are assumed to require one unit of foreign exchange in each sector except agriculture (assumed to require 1.25).

The choice between domestic production and imports is made by comparing the marginal direct and indirect use of capital in domestic production with the domestic price of imports. This procedure results in a decrease in the proportion of requirements in each sector which is imported as the price of foreign exchange rises.

3. *Exports*. The assumed demand functions for exports are given in Table 2B. The optimum level of exports in each sector will be that at which the marginal (direct and indirect) cost of producing exports is equal to the domestic value of the marginal revenue from increased exports. This optimum level will increase for higher prices of foreign exchange.

Solution. The techniques of solving linear programing problems need not concern us here, but the concepts are useful. In the present case it was possible to take advantage of the fact that the matrix of input coefficients can be made almost triangular—i.e., the interdependence is almost all in one direction, as shown in Table 1. This characteristic makes it possible to solve the problem without inverting the matrix of coefficients, which saves on solution time and also makes it easy to handle the demand functions for exports which have been assumed. The concept of "shadow price" plays a key role in the solution. It measures the total use of scarce resources in the economy to produce a given commodity. In the present case shadow prices are expressed in

terms of investment cost. The shadow prices of other basic factors whose supply is limited—foreign exchange and labor—are measured by their opportunity costs. Given the prices of these resources, the shadow price of each commodity consists of its direct capital cost plus the sum of all its inputs multiplied by their shadow prices. The optimum solution is reached by comparing cost of securing each commodity by alternative methods with the value given by its shadow price. This method is well suited to handle alternative production techniques when such data are known.

The usual method of solving a linear programing problem involves fixing the resource availabilities and output requirements and determining the optimum combination of activities which corresponds to these

limitations. In the present case it has proved useful to examine the implications of varying levels of availability of foreign exchange and labor. I have therefore assumed several combinations of the prices of labor and foreign exchange and determined the use of these resources corresponding to the assumed prices. The results can be plotted in a graph, as in Figure 2 on page 51, from which it is possible to determine the optimum prices corresponding to any levels of foreign exchange and labor. These prices in turn determine the activities used and investment in each sector.

* Including 416 billion of exports for which the demand is taken as given.

† Final demand less domestic production in excess of interindustry demand in the base year; i.e., the excess of projected total demand over net domestic availabilities in the base year Total requirements are equal to the increase in GNP plus the excess of imports over exports.

For each set of parameters, we have made several trials with varying prices of foreign exchange, holding the other parameters constant.[5] The results of these trials are shown in Table 4. Each one represents the solution requiring the minimum investment under the stated assumptions as to the values of the parameters. In the first three trials, an interpolation has been made at a constant deficit of 284, which was estimated to be the average amount of external resources necessary to achieve the desired increase in GNP within a ten-year period.

II. *Key Factors in Industrial Development*

I will now investigate the effects of differences in resource endowments, factor proportions, savings levels, and other basic factors on

[5] All the calculations on the aggregated model were made by Kenneth Kretschmer.

the optimum patterns of economic development. The hypothesis underlying this study is that industrialization may play a very diverse role in different types of country. Where structural disequilibrium exists, it is almost impossible to determine from the price system the true weight which should be given to these factors in investment decisions.

Variation in the underlying structural factors is reflected in a formal model through differing values of some of the parameters. Here I will
FIGURE 1 SUBSTITUTION BETWEEN CAPITAL AND LABOR

analyze effects of variation in the parameters related to three basic characteristics of developing economies: (1) factor proportions; (2) availability of foreign exchange; (3) the rate of growth.

Factor Proportions. The optimum pattern of economic development obviously varies widely with the endowment of available economic resources. Individual mineral resources, specific types of agricultural land, etc., are reflected in the capital requirements of individual sectors and determine the desirability of specific types of primary production. They require little comment. The relative abundance of larger categories of economic factors—aggregate natural resources, labor, and investment funds—is subject to more general analysis. The most sig-

nificant relationship is that between population or labor force as a whole and natural resources plus capital stock. It is often suggested that in the "overpopulated" areas, where pressure on the developed resources—primarily agricultural—is high, industrialization is more desirable than in countries where a shift of the labor force from agriculture to industry (without investment or technological improvement) would cause a significant fall in agricultural output.

Population pressure may affect several parameters in the model. In the first place, it means that there will be a fairly unlimited supply of labor available for nonagricultural employment. This labor is not a free good because—at least in part—it must be moved to towns, housed, and trained. In our system, this means that labor will have a shadow price or capital cost greater than zero but in all probability considerably less than the actual wage rate. In other cases, the opportunity cost of labor may equal or exceed its wage.

The over-all possibility of substituting labor for capital with fixed input coefficients is shown in Figure 1. Point *C* corresponds roughly to existing wage rates in Southern Italy, while point *A* represents the optimum solution with labor as a free good. The variation in total capital requirements corresponding to this change in the use of labor is not large—about 5 per cent—because the composition of imports and exports is the only factor which has been allowed to vary; techniques of production and the composition of final demand have been kept constant.

This variation in the optimum investment pattern takes place largely in the industrial sector. When the price of nonagricultural labor is taken at approximately the existing wage rate (no opportunity cost is assigned to agricultural labor, on the theory that even the most successful investment program will leave it in surplus supply), the fraction of total investment going into industry in the optimum program is 43 per cent. ("Industry" includes mining and manufacturing and excludes power and other services. See Table 4 above.) When both types of labor are "free," the optimum share of industry is increased to 55 per cent. (These proportions refer to "productive" investment, which is perhaps 70 per cent of the total investment taking place.)

Population pressure is also likely to be reflected in the relative levels of the marginal capital coefficients in agriculture and industry. In an overpopulated area, land is utilized more intensively in agriculture, and the capital required to extend the land under cultivation through reclamation, irrigation, etc., is greater. Densely populated areas are also likely to have fragmented land holdings which make mechanization less productive. To take two rather extreme examples, the marginal capital requirements per unit of output in agriculture in Southern Italy

are perhaps three times as high as they are in Turkey. There is little difference in the capital requirement in industry, however.

A variation in the capital/output ratio in agriculture will be reflected in changes in the desirable levels of investment in all the industrial sectors if a given increase in GNP is to be achieved. In the present instance, a lowering of the agricultural capital coefficient by about 15 per cent produced a decrease in the share of investment going to industry of about 20 per cent. Only the food processing industries increased their output. These particular values of course depend on the variability of capital coefficients within agriculture and industry.

Both of these aspects of the factor proportions problem thus appear to be quite significant in determining the role to be given to industrial investment. The importance of the "employment ratio" may be overstressed in actual practice, however, when it is divorced from the over-all test of increasing national income.

Availability of Foreign Exchange. The ability of a country to secure foreign exchange is another key factor in determining the desirable extent of industrial development. Industrialization consists pri-
FIGURE 2. EFFECT OF THE PRICE OF FOREIGN EXCHANGE ON THE TRADE DEFICIT

marily in the substitution of domestic production of manufactured goods for imports. The choice between domestic production and imports should be based on the scarce resources required by each alternative. In a linear programing model, this decision is based on the shadow price of foreign exchange, which is determined by the opportunity cost of domestic production in the marginal importing and exporting sectors. In equilibrium, the price of foreign exchange becomes the reciprocal of the marginal productivity of investment in these sectors.

The effect of changes in the price of foreign exchange on imports and exports is shown in Figure 2. The import curve represents the total demand of the economy for imports, taking account of optimum readjustments in domestic production at each price of foreign exchange.

The effect on the investment decision in any sector of a rise in the price of foreign exchange will be determined by three factors: (1) the rise in the price of imports of the commodity produced; (2) the variation in direct capital and labor costs in the sector; (3) the rise in the cost of materials purchased from other sectors. Investment in other sectors will cause the price of purchased materials to rise less than the price of imports. These external economies will affect primarily the finished goods sectors, where investment will be more attractive. As will be noted below, errors of partial analysis are largest in those sectors.

The export curve represents the combined effects of variations in supply and demand at each price of foreign exchange. Although constant capital coefficients were assumed, the rise in price of materials purchased by the export sectors serves to reduce the elasticity of supply, particularly for finished goods.

The optimum or equilibrium price of foreign exchange is determined by the ability of the area to sustain an excess of imports over exports through external borrowing or subsidies. In the present example, substantial subsidies are necessary to achieve the desired increase in national income, and the annual trade deficit is almost 7 per cent of GNP. One effect of such outside assistance is to permit the region to specialize to a greater extent in the less capital-intensive activities and secure a given increase in regional income with a somewhat smaller use of capital. Since many branches of industry are less capital intensive than agriculture in the present model, a higher deficit results in a greater proportion of investment going to industry. In other countries, the opposite result might well occur, however.

Since the equilibrium price of foreign exchange determines the limits to which investment should be carried in each sector where exports and imports are possible, it is the most crucial parameter in formulating a development program. If too low a value is used, for example, the

trade deficit will be larger than can be financed and emergency measures to stimulate exports or reduce imports will have to be taken. These will lead to investment at lower rates of productivity than would be the case if the proper exchange rate had been used throughout the program. The resulting increase in total cost of the program is illustrated in Section III below.

The Rate of Growth. The rate of growth affects the pattern of investment in two different ways. In the first place, foreign exchange earnings are fairly independent of the rate of growth. Except for improvements in technology or possible economies of scale in export production arising from a larger domestic market, foreign exchange earnings depend on the exchange rate and the elasticity of foreign demand for such exports. Imports, however, will increase with the rate of growth unless the exchange rate is changed, as shown in Figure 3. Even if foreign borrowing depends to some extent on the growth in national income, there will be a tendency for the net deficit to be greater at higher rates of growth.

In order to limit the trade deficit of foreign exchange availabilities a higher price must be given to foreign exchange. In the present example, an increase in the rate of growth by 10 per cent would have increased the exchange rate needed to maintain a constant deficit by 2 per cent. The marginal productivity of investment would fall by the same amount. Although this effect is not significant for small variations,
FIGURE 3. EFFECT OF GROWTH ON IMPORT REQUIREMENTS

when the growth rate is greatly accelerated it may become quite important. Higher growth rates lead to a greater need for self-sufficiency unless export demand is highly elastic.

The rate of growth will also act on the composition of investment through its effects on final demand. As per capita incomes increase, the proportion of income spent on manufactured consumer goods of all kinds may be expected to increase. The study of consumption in Southern Italy on which the final demand in the present model is based showed an income elasticity of demand of 1.35 for all manufactured goods (except food). The proportion of national income spent on investment goods is also likely to increase. Both of these factors will lead to an increasing proportion of investment in industry.

Both the increased demand for imports and the shift in the composition of final demand to more manufactured goods tend to give an increased importance to industrial investment at higher rates of growth. The increased pressure on foreign exchange may affect the desirability of investment in agriculture as much as in industry in some countries, but there are more likely to be technological limits to a rapid increase in agricultural output through increased investment. Throughout this discussion I have left out of account technological improvement in agriculture, which may be one of the most important elements in increased output. The rate of technological progress in agriculture is limited by other factors, however. This conclusion appears to have particular force in an overpopulated area like Southern Italy, where a further increase in the rate of growth in the agricultural sector can only be secured at very high capital/output ratios.

III. *Structural Interdepedence and Investment Priorities*

The preceding section has illustrated the way in which the decisions affecting industrialization depend on resource availabilities and investment in requirements in all sectors. The interdependence among sectors introduces errors into any method of making investment decisions based only on the characteristics of single sectors or projects. I shall now try to analyze these errors and suggest methods of improving partial methods from the experience gained in solving a general equilibrium model.

Errors in Partial Analysis. Partial analysis uses the same general test for investment allocation as does linear programing: the marginal productivity of investments included in the program should be greater than those which are excluded. The marginal productivity may not be equal in each sector because of limitations on the commodity composition of output even though a perfect price system would bring about such equality. With either method, an optimum program satisfying

the various resource limitations can only be arrived at by trial and error. There are various routes by which the final solution can be reached, but a convenient method in both cases is to assume a marginal productivity of investment, to exclude projects falling below this figure, and then to see whether investment funds have been exhausted and other limitations satisfied. In the partial analysis it is possible to take account of some errors in the price system, such as the existence of a tariff on imports of the product, but not of the indirect effects of such errors on the price of purchased materials.[6]

As has been pointed out earlier, the partial analysis is subject to two general types of error arising out of interconnectedness: inability to determine how much of a given commodity will be required and the omission of external economies due to investment in other sectors. The first type of error is probably of greater quantitative significance. To measure it would require a comparison of the output forecasts which would be made in ignorance of the input-output pattern with the results of the present model. These errors would be small for finished goods and larger for intermediate products and producer services. Since the latter sectors have higher capital coefficients, the errors in estimating investment requirements would be greater than those in forecasting output. They cannot be measured here for lack of a basis of comparison, however.

The second type of error—omission of external economies—can be isolated by assuming the same knowledge of the interdependence of output in both cases and the use of constant current prices in determining which commodities shall be domestically produced and which imported. The partial method would therefore assume a constant ratio of value-added to total output in each trial. To compare this method to the linear programing model, I have made a solution corresponding approximately to trial A5 in Table 4 in that the increase in GNP is almost the same (see trial E, Table 4). The differences between these two solutions show the magnitude and also the nature of the errors in the partial method.

In terms of the over-all test of capital requirements (labor being assumed free in this trial), the difference of about 115 billion lira (corrected for the difference in GNP) is not large—about 4 per cent of total investment requirements. If we limit the comparison to the marginal cases in which external economies have some significance, however, this difference is much more important.

The best indication of the inefficiency of the partial method is the fact that the marginal productivity of investment (the reciprocal of

[6] A suggested method using partial sector analysis has been given in my "Application of Investment Criteria," *Quart. Jour. Econ.*, February, 1953, pp. 76-96.

the price of foreign exchange) with the partial method is much lower—28 per cent as compared to 35 per cent for linear programing. This difference results from the fact that external economies are not taken into account and underinvestment in some sectors results. In other sectors, investment must be pushed to lower levels of productivity to secure the same increase in GNP. There will be underinvestment in the sectors which purchase a large amount from other sectors, as in the production of finished goods. Textile production in the present case was 40 per cent lower with the partial method than with linear programing. Conversely, there will be overinvestment in primary production and basic industries to compensate for the first error; agriculture is 30 per cent higher with the partial method.

Regardless of the values of the various parameters, there will be this systematic bias in favor of primary production and basic industries and against finished goods when external economies are ignored. These biases also extend to the export sectors.

Planning Industrial Development. To improve on partial analysis, some of the effects of structural interdependence must be taken into account. The methodology which has been used here may be helpful even when all the elements are not known. This method takes advantage of the fact that interdependence in the economy is not general, but is largely "one way." The demand for basic materials depends on the demand for finished goods; the demand for minerals and agricultural products depends on the first two categories; and, finally, the demand for fuels, power, transport, and producer services depends on all of the others. The extent of this one-way interdependence in the Italian economy is shown in Table 1; less than 5 per cent of the interindustry flows occur to the right of the diagonal when the sectors are arranged in such a way as to minimize such circular interdependence. To compute output requirements we should start with the sectors at the top of the list, while to trace out the effects of external economies on prices we should start at the bottom.

A procedure which will introduce some of the elements of a general equilibrium analysis into the usual sector approach is the following:

1. Divide the economy into as many sectors as can be managed and arrange them in the order of maximum one-way interdependence as indicated in Table 1.

2. Within each sector, rank projects according to their marginal return on investment, using expected prices and correcting for tariffs, subsidies, etc., where possible.

3. Estimate the final demands in the economy which would result from the increase in income expected from the investment program.

4. Using an assumed marginal productivity of investment, exclude

projects in each sector which have lower returns, wherever there is the alternative of importing. Include all export projects which exceed this rate of return. Start at the bottom of the list in making this estimate (with services and primary production) and revise the cost of purchased materials where possible on the basis of previous decisions as to imports or domestic production.

5. Starting at the top of the list of sectors, compute the required output in each from the final demand and the estimated use in preceding sectors. Compute imports, exports, and the payments deficit.

6. Revise the size of the program downward if the available investment funds have been exceeded. Revise the productivity of investment downward if the trade deficit is excessive. Repeat the calculation until limits on investment, foreign exchange, and other resources are satisfied.

It would require a paper much longer than the present one to explore the practical problems involved in each of these steps. They will vary greatly depending on the type of information available. One great advantage of using such a framework for investment analysis, however, is that it can incorporate whatever fragmentary information is available from a variety of sources—engineering studies, demand analyses, import statistics, etc. This approach merely makes the judgments which will be made in any case more consistent.

IV. *Conclusion*

The role of industrialization in economic development cannot be evaluated by looking only at individual sectors. This paper has explored the ways in which our judgments may be modified by looking at the total effects of an investment program. To make this investigation, I have had to abandon the *ceteris paribus* assumptions of partial equilibrium analysis and work with a general equilibrium system. Although some of the parameters are estimated from very inadequate evidence, the most important elements—the input coefficients—are the most reliable. Few of the above conclusions would have been changed by large deviations in the other parameters.

Knowledge of structural interdependence is particularly important in the industrial sectors of the economy. The external economies which occur in these sectors provide the justification for investment in "social overhead" facilities and in much of primary production. The desired level of output in each industrial sector depends on developments in the others. We have seen that factor proportions, comparative advantage, and the rate of growth all affect the amount and type of industrial investment which is desirable. My main result, therefore, has been to stress the need for over-all analysis in planning industrial development.

INVESTMENT IN AGRICULTURE IN UNDERDEVELOPED COUNTRIES

By William H. Nicholls[1]
Vanderbilt University

"Ill fares the land, to hastening ills a prey,
Where wealth accumulates, and men decay."
—Goldsmith, *The Deserted Village*

In this paper I shall assume that development policy in underdeveloped countries has, as its minimum objective, an increase in per capita real national income. However, in considering the place of agricultural investment in general economic development policy, I prefer to use a more rigorous standard of economic progress which also takes the distribution of the (larger) national income into account. More specifically, I shall define economic progress as a rise in per capita real income which is in some degree shared by every sector of the economy. This means that I am unwilling to accept as economic progress the alleged gains (essentially a statistical mirage) which may result from subsidizing a parasitic type of development in one sector by means of direct or indirect levies on other sectors, which are made worse off in the process. It also means that, at least in a long-run context, I insist that agriculture and its major subsectors must share in any real gains in per capita national income if we are to consider the claims of successful economic development valid. At the same time, I shall argue that—quite apart from such equity considerations—sustained economic development is impossible if it is sought on the basis of agricultural policies which promote the interests of a few of the larger commercial farmers without concomitant attention to progress within the broad base of essentially subsistence agriculture so characteristic of most underdeveloped countries.

Due to the limitations of space and my own foreign experience, I have decided to confine my treatment of an extremely broad subject to a case study of one prominent underdeveloped country, the Republic of Turkey. I shall review Turkey's remarkable expansion in agricultural output in recent years, shall seek to appraise the extent to which its ambitious agricultural development program has contributed to this expansion, and shall conclude with a discussion of the lessons to be learned from Turkey's recent experience.

[1] I am indebted to G. E. Brandow, Murray Ross, T. W. Schultz, Frank T. Bachmura, Anthony M. Tang, and Roger Weiss for their helpful criticisms of an earlier draft of this paper.

I. *Recent Agricultural Development Policies in Turkey*[8]

When I was in Turkey in 1950 as a member of the International Bank mission, even Turkey's limited industrial output was piling up in inventories because of lack of purchasing power on the part of its dominant peasant population. The 1949 cereal harvest had been extremely poor, resulting in a sharp reduction in national income, and several hundred thousand tons of wheat had to be imported. Partly under the prodding of the ECA mission, accompanied by considerable financial and technical assistance from abroad, the Turkish government had already embarked upon a substantial agricultural development program. This program put major emphasis upon farm mechanization and high cereal price supports. Mechanization was justified on the grounds that it would put Turkish wheat and cotton on a substantial export basis by which the foreign exchange for farm machinery (including spare parts and fuel) might be more than recouped. The two agricultural specialists of the Bank mission, of which I was one, were extremely skeptical of the prospects that mechanization and price supports would prove to be very effective means of expanding agricultural production.

Our skepticism resulted from the fact that the typical Turkish peasant had only ten to fifteen acres of land, which appeared to be far too small to make mechanization economically feasible or high price supports a very effective stimulus to increased output. Even on larger holdings, fragmentation often offered a further deterrent to mechanization. Hence, our Bank mission report emphasized the importance of improving rural transportation, communication, and marketing facilities so that Turkey's several million peasant families might be more fully integrated into a single national market economy. We also strongly recommended expanded and improved agricultural research and extension services, public farm credit, and direct subsidies for the adoption of recommended farming practices, directed at helping the peasant increase his output from his few acres of land.

In making these recommendations, we assumed that, given its prevailing primitive production and marketing techniques and small landholdings, Turkish agriculture had a very low short-run elasticity of supply. Hence, we supported longer run public policies which we believed would lower its whole supply schedule. However, we emphasized

[8] This section draws heavily upon the following source materials: G. E. Brandow, *Agricultural Development in Turkey*, Foreign Operations Administration, Ankara, Dec., 1953, mimeo., pp. 2, 7, 9, 11-21, 26, 36-37, 40-42, and 55; *The Economist*, May 15, 1954, Special Insert on "Turkey," pp. 1, 4-5, and 11. International Bank for Reconstruction and Development, *The Economy of Turkey*, Report of a Mission, Washington, 1951, especially Chap. V; International Monetary Fund, *International Financial Statistics;* United Nations, *Statistical Papers*, Series H; and U. S. Dept. of Agric., *Foreign Crops and Markets* and *The Wheat Situation*.

the importance of finding improved techniques which were not laborsaving and which, being adapted to small-scale operations, did not need to await farm enlargement in order to raise agricultural productivity. On the other hand, we seriously questioned the use of high price supports, either with existing primitive techniques or with government promotion of new techniques which would substitute much scarce capital for an already redundant labor supply while benefiting most a relatively few medium to large landholders.

Despite our recommendations, the Turkish government continued to put major emphasis upon farm mechanization and high price supports. The number of tractors, which had already grown from 2,500 to 10,000 during 1948-50, continued to increase to 35,000 (well in excess of Brazil's 22,000-30,000) by 1953. Furthermore, following the upsurge in world wheat prices resulting from the Korean war, the Turkish government continued to advance its very high price supports on cereals as export prices weakened substantially after 1951.

Of course, Turkey's agricultural development program was not limited to mechanization and price supports. Between 1948 and 1952, the Agricultural Bank of Turkey increased its outstanding public farm credit (albeit by inflationary means) more than fourfold, with about one-third of the increase in direct loans to farmers earmarked for machinery and equipment purchases. The excellently managed road-building program helped to bring more Turkish farmers and idle land into the market economy. The government distributed about 1.8 million acres of previously uncropped land to families and villages, and the amount of land under irrigation increased by about 15 per cent. The public seed-improvement program made considerable progress and the supply of fertilizers (two-thirds imported) increased more than fivefold. Agricultural research and extension activities also were gradually expanding but, with the major appropriations going to the independent price support and agricultural credit agencies, the 1953 budget of the Ministry of Agriculture was still only about 25 million dollars.

Whatever the combination of reasons, it is certain that Turkey did enjoy a remarkable expansion in agricultural output during 1948-53. Cereal production increased from 9.0 to 14.3 million metric tons and cotton lint production from 58 to 140 thousand metric tons. Wheat exports rose from nil to 587,000 tons, Turkey (thanks to Argentina's default) achieving at least temporarily fourth place among the world's wheat-exporting nations. Cotton exports rose from 16,000 to 100,000 metric tons. In 1952, the index of Turkish agricultural production was 47 per cent above its 1948 level, and the index of industrial production was 33 per cent higher (a year later 49 per cent higher). According

to the *Economist,* Turkish national income (in current prices) increased from 8.1 to nearly 12 million Turkish liras during 1948-53 while per capita national real income increased 21 per cent during 1950-53. If these data are correct, they indicate that per capita real income—which approximated its 1938 level in 1948 and 1950 and stood at only 84 per cent of 1938 in the bad harvest year 1949—rose spectacularly during 1950-53.

Frankly, I suspect that the actual rise in Turkey's per capita income was considerably less. At least it is quite possible that faulty price deflators and the dominant importance of agriculture (with its heavy dependence upon natural conditions which were extraordinarily favorable during 1951-53) have served to exaggerate the extent and permanence of Turkey's recent economic progress. Furthermore, as we shall see later, nature and economic events have taken a less favorable turn during the past year. Nonetheless, having seen and sensed the great strength of Turkey's will to progress, I feel confident that—however uncertain the quality of Turkish national statistics—the recent pace of its economic development has in it much of real substance. Hence, an appraisal of the virtues and shortcomings of Turkey's recent agricultural development policies would appear to be in order. Before doing so, however, let us look briefly at the recent expansion of two major Turkish crops—cereals and cotton—and attempt to assess the factors responsible for the increased production of each during 1948-53.

Cereals, produced under semiarid conditions, account for around 85 per cent of Turkey's cropland harvested and for perhaps 40 per cent of its net agricultural income. In his recent study, Professor Brandow found that a significant part of the sharp increase in Turkish cereal production during 1948-53 was due to weather, which was unusually favorable during 1951-53. Thus, he estimated that 1953 cereal yields were 22 per cent higher than normal weather yields with improved practices then in use; that weather alone caused 1953 yields to be about 10 per cent above 1948, when growing conditions were also above average; and that, in conjunction with increased area, this higher yield accounted for nearly one-fourth of the increase in cereal output during 1948-53. Supporting Brandow's judgment about the importance of weather, the 1954 cereal crop (wheat and barley), with much less favorable weather, yielded one-third less per acre than in 1953. In light of previous experience, one would expect this decline in cereal production to be reflected in some decline in Turkey's national income for 1954. Nevertheless, Turkish cereal production in 1954 was more than double its 1949 low and, despite a 10 per cent lower yield, was still 26 per cent above its level in the good-weather year 1948. Thus, quite independent of the weather factor, cereal production has shown a marked increase since

1948—primarily because of the sharp increase in the area planted to cereals. During 1948-53, cereal acreage increased by 7.4 million acres (nearly 40 per cent), largely at the expense of poor-quality grazing lands and unused fields.

Undoubtedly, the most important factor in bringing about this increased area in cereals has been the Turkish government's high price support program. For the crops of 1952-54 (and, prospectively, for the 1955 crop), the government's *Toprak* office has been supporting wheat prices at levels about a third higher (at the official exchange rate) than present high US price supports. The effects of these supports on increased acreage have been further enhanced by improvements in transportation and a doubling of the number of government grain-buying stations. Although only about 12 per cent of the 1952 cereal acreage was cultivated with tractors, mechanization also contributed to the increased area by making possible the tillage of a larger area of cropland. Mechanization also helped to raise yields per acre, although only a strikingly small part of the increase in total cereal output was attributable to yield-raising practices (improved seed, fertilization, etc.) other than those associated with mechanization. According to Brandow's estimates (*op. cit.*. pages 40-41), with normal weather throughout 1948-53, expected cereal output in 1953 would have been 43 per cent higher than 1948 expected output. Brandow estimates that each of the following factors in isolation would (with normal weather) by 1953 have added the indicated percentage to 1948 normal output: favorable prices and markets (increased area), 12 per cent; mechanization (effects about equally divided between "increased area" and "improved practices"), 10 per cent; improved transportation (increased area), 5 per cent; seed improvement, 2 per cent; fertilization negligible; and area-increasing intangibles 14 per cent. Of the estimated 43 per cent increase in cereal output with normal weather, five-sixths was credited to increased area and only one-sixth to improved practices.

Cotton lint production in Turkey increased nearly threefold between 1948 and 1952, its acreage more than doubling and its yield per acre 25 per cent higher in the latter year. In 1953, with some cutback in acreage and yields, production was about 15 per cent lower (616,000 bales) but still about 2.4 times its 1948 level. Undoubtedly, a major part of this increased output was due to the tremendous boom in cotton prices which the Korea outbreak created. During 1950-51, Turkish cotton prices more than doubled and acreage expanded sharply as the United States put a temporary embargo on its own cotton exports. While subsequent declines in prices brought some contraction in acreage in 1953 and 1954, Turkish cotton acreage and production remained

well above their 1950 level and far above 1948. Meanwhile, mechanization of cotton proceeded at a rapid pace, 56 per cent of the cotton in the Mediterranean and Aegean regions being cultivated with tractors by 1952. Brandow has estimated that the normal-weather yield of seed cotton increased about 7 per cent during 1948-53 as a result of the use of improved practices on a greater proportion of the land in cotton. Meanwhile, the area in cotton doubled between the two years. Of the factors (other than intangibles) accounting for the increased area in cotton, he gives about equal credit to favorable prices and mechanization. Of the factors representing improved practices, he gives major weight to mechanization, with irrigation, seed improvement, and fertilization also making significant contributions to the increased output. On the assumption of normal weather throughout 1948-53, Brandow estimates (page 42) that each of the following factors in isolation would by 1953 have added the indicated percentage to 1948 normal output: mechanization, 53 per cent (via increased area, 24 per cent; via improved practices, 29 per cent); improved seeds, 10 per cent; fertilization, 6 per cent; and area-increasing intangibles, 8 per cent. Of the estimated 115 per cent increase in cotton output with normal weather, half was attributed to increased area and half to improved practices. However, Brandow emphasized that he assigned to increased area only the production that would be obtained from it by primitive methods. Hence, as he explicitly recognized, his methodology proved awkward for cotton, appearing to understate the importance of area.

So much said by way of summary and background, let us turn to an appraisal of Turkey's recent agricultural policies.

II. *An Appraisal of Recent Turkish Agricultural Policies*[8]

Turkey's farm mechanization program has probably received the most popular credit for the nation's recent agricultural progress. To what extent has this farm mechanization program been sound development policy? On the credit side, mechanization has made a significant contribution to both the area under cultivation and to higher yields. Brandow has estimated that about 17 per cent of the new land added to cultivation of field crops (17 per cent for cereals; 32 per cent for cotton) during 1948-52 was developed by tractors. A recent University of Ankara survey of mechanized Turkish farms found that—because of more effective, better timed, or more frequent tillage and seeding

[8] Most of the data in this section are derived from Brandow, *op. cit.*, pp. 9-10, 16, 23-24, 26, 41-42, 45, 53-54, and 56; and from *Economic and Social Aspects of Farm Mechanization in Turkey*, A Study by a Committee of the Faculty of Political Science, University of Ankara. Sponsored by the MSA (FOA) Mission to Turkey, Ankara, 1953, mimeo., pp. 6-8, 14-18, 20, 25, 30-36, 48-50, 62, 64-69, 70-76, 78-79, 83, 86-89, 91, 94, and 96-98. The latter survey, made in mid-1952, included a sample of 3,015 mechanized farm families, constituting about 4 per cent of all families in 448 of Turkey's most mechanized villages.

operations—mechanization produced substantially higher yields than did primitive techniques. Brandow's estimates also suggest that, exclusive of the weather factor, 23-25 per cent of the 1948-53 increase in "normal" output of cereals and cotton was attributable to mechanization. Furthermore, through 1952, Turkey's net investment in farm machinery had probably more than paid for itself in terms of increased foreign exchange earnings, net of costs of importing replacements, spare parts, fuel, and oil.

However, with export prices falling, with the existence of export surpluses of cereals highly dependent upon the vagaries of weather, and with the larger farms now substantially mechanized, these factors hardly justify a comparable rate of additional mechanization in the future. In fact, it is quite possible that mechanization of Turkish agriculture has already been carried too far. In 1952, the annual amount of cropland (owned, rented, or worked on a custom basis) cultivated per tractor on Turkey's mechanized farms was probably about 160 acres and the undepreciated machinery investment per acre of cultivated land was about $27. But 43 per cent of Turkey's tractors were in regions whose mechanized farms averaged only 49-86 acres per tractor. To be sure, the remainder of the tractors were in three regions with 165-496 acres per tractor. In the regions having the greatest numbers of relatively large farms, machinery investments per acre approximated that of medium to large commercial farms in the United States. Undoubtedly, many of the larger Turkish farms (if not too much fragmentized) can utilize existing farm machinery rather fully and might invest profitably in still more machinery, particularly complementary tractor-drawn equipment which has lagged behind the expansion in tractor numbers in Turkey. Nonetheless, it is clear that many of Turkey's mechanized farms are already well below the size considered necessary for reasonably efficient utilization of machinery in the United States, where labor is relatively much scarcer and where machinery and fuel are much less expensive and require no foreign exchange. Hence with only about 3 per cent of Turkey's 2.5 million farm families holding over 123.5 acres (a third or more in fallow), the number of tractors in Turkey would appear to be close to the saturation point pending substantial farm enlargement.

Through 1953, the Turkish farm mechanization program had probably directly benefited only 25,000-27,500 (scarcely over 1 per cent) of Turkey's farm families. These few families probably enjoyed average annual gross cash incomes in excess of $15,000 each and were the recipients of at least 25 per cent of the public farm credit outstanding to all Turkish farmers at the end of 1952. Such an initial concentration of agricultural credit upon the medium to large farms, whose produc-

tion can most readily respond to improved conditions, was probably wise. The extent to which such intermediate-term farm credit should have been almost wholly confined to machinery and equipment loans is less certain. Insofar as mechanization brought additional land into cultivation which would otherwise (at constant prices) have remained virtually unused, the value of additional output in excess of machinery investment and operating costs was a clear gain to the nation, since no agricultural workers needed to be displaced by the machinery. During 1948-52, the average tractor-owning family in Turkey increased its average acreage operated, exclusive of custom work, by 31 per cent. Brandow has estimated that two-thirds of this increase in cultivated area was previously uncultivated. To the extent that this was true, Turkey's mechanization program would appear to be largely warranted, assuming that the new land would not otherwise have been brought under cultivation.

On the other hand, to the extent that mechanization resulted in tractor-owning families acquiring additional land previously cultivated by others, the answer is much more complex. In this case, the increase in gross value of product per acre—whether by an increased yield of the same crop or by the substitution of a more intensive crop—attributable to mechanization is less likely to exceed the net costs of the mechanized techniques. Furthermore, the social problem of displacing agricultural workers by machinery may well arise. Of course, insofar as tractor-owning farmers acquire by rental or purchase the use of previously cultivated land from owner-operators, the displacement is presumably voluntary, with the former operators somewhat better off than before. However, the same is not true if the additional land acquired by mechanized farmers was previously cultivated, for these or other landlords, by tenants and sharecroppers. Under the latter circumstances, the mechanized farmers might achieve large economic gains while displacing former tenants or sharecroppers who lack alternative employment opportunities.

The Turkish mechanization program has apparently already unduly encouraged such deleterious social effects. With the increasing pressure for additional land in Turkey's mechanized villages, land disputes have become more frequent, while marked changes in land tenure have followed mechanization. Sharecropping has decreased while cash rental of land has increased, with a larger proportion of landowners working their own land since mechanization. At the same time, the percentage of mechanized farmers who hire farm workers has increased but the number of full-time hired workers has tended to decline in favor of temporary hired labor during the busy seasons only. With mechanization increasing the seasonality of labor requirements, temporary migra-

tory labor has become more important, and cash wages have largely displaced wages in kind. Thus, insofar as Turkish mechanized farmers have taken over land previously cultivated by tenants or sharecroppers, the latter appear to have suffered a steady reduction in their share of the crop, usually ending either in a shift to the status of seasonally hired day labor or in complete displacement.

Upon the basis of the University of Ankara survey, I have estimated that each new tractor during 1948-52 resulted in the gross displacement of about 3.4 sharecroppers. Projected to all Turkey, these estimates suggest that around 79,000 sharecroppers (71 per cent of them in the two major cotton regions) were so displaced, about 64,000 of them remaining in their villages. By regions, the displacement ratio was 8.9 sharecroppers per tractor in the Mediterranean, 5.9 in Southeastern Anatolia, 0.8 in Central Anatolia, and 1.8-2.4 in the other three survey regions. Of course, some of the sharecroppers—especially those who were able to obtain well-paid and *nouvelle élite* jobs as tractor drivers or mechanics—improved their well-being as hired workers. Particularly, the doubling of cotton acreage was an important offset to otherwise declining labor requirements, and it is significant that the survey villages apparently experienced considerable net in-migration during 1948-52. Nonetheless, against the gains through increased yields per acre to the mechanized farmers, some of their hired workers, and the nation must be weighed the probable substantial net increase in numbers of underemployed villagers who, lacking alternative farm or nonfarm employment opportunities, have had considerable reductions in income. This income-distribution problem has been further aggravated by the fact that even the wealthiest Turkish farmers pay no income taxes on soil products and only negligible property taxes.[4]

To sum up, the Turkish farm mechanization program has probably been justified to the extent that it has been an independent factor in increasing the nation's total cultivated area. Where it has involved taking over land previously cultivated by owner-operators, its economic contributions are less certainly positive but its social costs have been negligible. But insofar as it has displaced tenants and sharecroppers

[4] Cf. Ankara Faculty, *op. cit.*, pp. 48-50; and Richard D. Robinson, "Tractors in the Village—A Study in Turkey," *Jour. Farm Econ.*, 1952, pp. 451-462. By way of contrast, mechanization of cotton in the Southern United States has thus far avoided these important social costs. While the effects of mechanization upon tenure status have been strikingly similar in Turkey and the American South (cf. Harald A. Pedersen and Arthur F. Raper, *The Cotton Plantation in Transition*, Miss. Agr. Exp. Sta., Bul. 508, 1954), few if any sharecroppers have been displaced in the United States. Instead, as better job opportunities have developed elsewhere, largely outside of agriculture, Southern sharecroppers have voluntarily migrated on a large scale. With agricultural labor becoming scarcer and wage rates higher, Southern plantation owners have been forced to mechanize in economic self-defense.

without concomitant expansion of better alternative employment opportunities, it has already pressed beyond the limits of Turkey's present socioeconomic structure. Certainly, any further increase in the number of what might be called "Bayar's oxen" (tractors) should largely await more "Ataturk minarets" (smokestacks).

Nevertheless, the recent great influx of tractors (less than one-fourth of them via Marshall Aid) has become the symbol of Turkey's agricultural renaissance. And one should not dismiss too lightly the importance of symbols in inspiring an underdeveloped country with a strong will to make progress. However, the arrival of the tractor has not directly helped Turkey's 2.5 million small farmers, of whom a substantial majority still use wooden plows and a negligible number use even simple animal-drawn grain drills. At the same time, the tractor has diverted far too much public attention and resources away from the peasantry which constitutes 65-75 per cent of the Turkish population.

Thanks to a combination of favorable circumstances (including the fortuitous events of the Korean commodity price inflation and extraordinarily good weather), Turkey has achieved a remarkable agricultural expansion since 1950. In view of this success, the recommendations of our Bank mission report respecting Turkish agricultural development undoubtedly appear, with the benefit of hindsight, to have been overly cautious and pessimistic. It is clear that we underestimated the opportunities for expanding rapidly Turkey's total area under cultivation. We recognized in 1950 that Turkey faced considerable difficulty in even maintaining its modest level of per capita food consumption. We further recognized Turkey's heavy dependence upon raw agricultural land (in 1951 purchased inputs and depreciation amounted to only 19 per cent of Turkey's gross farm income) in expanding its food supply but failed fully to appreciate the possibilities of increasing the inputs of cultivated land. Apart from increased cultivated area and shifts from livestock to cereals, Turkey can increase its agricultural output relatively little by transferring resources from nonfarm sectors to farms because so large a part of its total resources is already employed in agriculture and because so small a part of its agricultural resources is supplied by the nonfarm sector which, in turn, cannot readily employ those agricultural resources (labor) in substantial oversupply. In the United States, on the other hand, less than 10 per cent of its resources are committed to agriculture and a large part of American agriculture's production expenses (two-thirds of gross farm income) represents inputs that are either purchased from, or can readily be employed in, the nonfarm sector. Under these circumstances, the United States can (with little change in the area of agri-

cultural land) quickly expand its food supply in time of war or other emergency whereas most underdeveloped countries (given a constant land supply) can expand theirs little if at all. (T. W. Schultz, "The Supply of Food in Relation to Economic Development," *Economic Development and Cultural Change*, December, 1952, pages 245-247.)

During 1948-53, while the total area planted to crops expanded from 23 to 32 million acres, the area in cereals grew from 20 to 27 million acres and, according to Brandow, may ultimately reach a maximum of 32 million acres. Clearly, most of this increased cultivated area must have been developed with traditional primitive methods, implying that many nonmechanized farmers were given the incentive (through higher prices and improved highways) to work harder than before. Furthermore, it demonstrates that the elasticity of supply was higher at relative farm prices above those prevailing in 1950 than we might have expected.

To a large extent, however, this kind of elasticity was not relevant because 1950 prices (particularly for cereals) were already too high, given existing high-cost, low-productivity production methods. In other words, much of the land recently brought under cultivation would have continued, except briefly during the Korea-induced price flurry, to be submarginal (with unchanged techniques) in the absence of the subsequent rise in already high cereal price supports. Furthermore, since the expansion of cereals was largely at the expense of pastures, a serious imbalance in Turkey's livestock economy is at hand. During 1948-52, the total number of sheep, goats, and cattle continued to increase in spite of a 20 per cent reduction in pasture area, resulting in intensified overgrazing even though moisture conditions (except in 1949) were very favorable. Hence, pasture and livestock improvement and expanded production of feed grains, largely neglected to now, loom even larger as a major problem for further agricultural development. Only insofar as the increased area in cultivation would have resulted, at constant or lower relative prices, from recent improvements in transportation, the growth of government buying stations, and mechanization (i.e., by factors which shift the supply curve to the right) can it be counted as a clear economic gain. Otherwise, only if the reduction of the supply in response to a lowering of price supports would be substantially less elastic than the actual expansion which followed higher price supports (a not unlikely prospect) can the expanded area be counted as a further partial gain to the Turkish nation. Hence, given the relatively small importance of improved practices (apart from those resulting from mechanization) in Turkey's recent agricultural expansion, our recommendations for increasing the productivity of existing cultivated land, pastures, and livestock need renewed emphasis at the present time.

III. *Lessons from the Turkish Experience*[6]

Clearly, Turkey deserves credit for recognizing, after a long period of forced-draft industrialization and sad neglect of its agriculture, that agricultural development is of co-ordinate importance in balanced economic progress. However, as the recent unfavorable turn of events in the Turkish economy is now making clear, the Korean war and several years of excellent weather were not unmixed blessings despite the temporary boost they gave to agricultural development in Turkey. While the Korean war gave a brief fillip to world wheat markets, the subsequent rise in world wheat stocks (at an all-time high in mid-1954) and the fall in world prices have pushed Turkey into increasingly heavy export subsidies, estimated at more than 40 million dollars on the 1953 wheat crop alone. Only thus were the Turks able to dispose of their wheat surplus abroad (much of it through unsatisfactory barter deals with Spain, Yugoslavia, and other non-EPU countries) in spite of its high price, poor quality, and lack of standardization. Furthermore, it now appears that Turkey's poor 1954 cereal crop has eliminated for the current year any export surplus, some 500,000 tons of wheat imports being in prospect to meet urban food needs. Similarly, during the 1953-54 season, Turkish cotton exports of 377,000 bales (60 per cent of domestic production), while at the second highest level in history, were down 14 per cent from a year earlier. More significant, the bulk of Turkey's cotton trade shifted from Western Europe to non-EPU countries with which it made barter arrangements, the latter's share increasing from 22 to 64 per cent in a single year.

Thus, the temporary opportunity to sell at high prices cereals and cotton of poor and unstandardized quality was permitted to divert attention from the importance of adopting promptly a modern system of grades and standards, in the absence of which Turkish exports now face strong resistance in world markets. Furthermore, cereal production has not yet been put on the more efficient basis necessary if it is to be able to continue at its recent high level without abnormally good weather and present huge public subsidies. In the process, the hope that wheat and cotton exports would play a large part in solving Turkey's foreign trade problem has been only partially realized, while the considerable potential of its livestock economy has continued to face official neglect. Meanwhile, in seeking to encourage agricultural expansion, the Turkish government has used centralized con-

[6] The data in this section are based upon Brandow, *op. cit.*, pp. 9-10, 53-56; Ankara Faculty, *op. cit.*, pp. 25, 30-31; *The Economist, loc. cit.*, pp. 1-2, 4-5, 10-12; and recent issues of United Nations, *Monthly Bulletin of Statistics*, and U. S. Dept. of Agric., *Foreign Crops and Markets* and *Foreign Agriculture Circulars*. Cf. *The Economy of Turkey, op. cit.*, especially pp. 67-73, and William H. Nicholls, "Domestic Trade in an Underdeveloped Country—Turkey," *Jour. Pol. Econ.*, 1951, pp. 463-480.

trol—exercised through the public grain monopoly and the nominally private large agricultural sales co-operatives—to short-cut many problems of transport and communication (e.g., grading and market news service) whose solution is a prerequisite to the development of efficient private farm marketing enterprises.

Despite the tremendous expansion of agricultural credit, the Turkish government has continued to concentrate (apart from machinery credit) on short-term production credit which has done little to build up the farmer's permanent productive capacity. Insufficient attention has been given to the evaluation of loan applications and to the supervision of the uses to which loans are put. As a result, the distribution of farm credit has been far more haphazard and less productive of improved farming practices, especially for small farmers, than it might have been. Similarly, high price supports have not benefited small peasants much because they have so little to sell. In fact, it is clear that, with half of its budget devoted to defense, Turkey has pushed agricultural development largely via the inflationary route. The manifold increase in credit, especially agricultural, and the method of financing the cereal subsidy and the stock-piling of cereals have greatly increased inflationary pressures. At the end of 1953, the supply of currency and demand deposits was 75 per cent above its 1950 level. The cost-of-living index (1948 = 100) moved from 104 to 112 during 1950-53 and then in the first half of 1954 climbed rapidly from 113 to 128. Despite the poor 1954 cereal crop, Turkey should be able to maintain during the current crop-year its per capita cereal consumption at somewhat above its 1948-49 level. However, the probable high income elasticity of demand for cereals among urban workers with rising money incomes may (despite large wheat imports) favor further inflation, especially if producers should maintain their recent level of cereal consumption at the expense of marketings.

By mid-1954, the Turkish government was forced by these unfavorable developments to embark on at least a limited anti-inflation program, largely aimed at restriction of nonessential imports. It is to be hoped that, in the process, it will also scale down to more manageable levels its overgenerous distribution of agricultural credits (particularly for machinery), its present excessive cereal price supports, and its more ambitious large-scale irrigation schemes, while imposing a heavier tax burden on at least its richer farmers. Such a reversal of recent inflationary policies, which helped to keep Turkey's Democratic Party in power by a thumping majority in May, will require much economic wisdom and political courage in high places. Nonetheless, it should now be clear that indiscriminate mechanization, credit expansion, and price inflation have not proved to be the easy way out that they once ap-

peared. While moderation of these policies might result in some contraction in present agricultural output, the social costs of subsidizing present inefficient farming techniques are far too heavy for so poor a country as Turkey to bear them much longer.

Such counsel does not mean an abandonment of Turkey's agricultural development objectives. Rather, it means a shift of emphasis to other means which will more adequately meet the fundamental needs of Turkish agriculture, particularly those of its dominant peasant population, over two-thirds of whom have landholdings of less than 12.3 acres and nine-tenths less than 24.7 acres per family. In my opinion, the solution lies in the Turkish government at last facing up to the plight of its villages by developing a direct, determined, and persistent attack on the low productivity which lies at the roots of village poverty. Like other underdeveloped countries, Turkey has tended to follow—first in industry, now in agriculture—what I would call the "showcase" type of economic development. That is, at the expense of the population at large, some small group of producers is heavily protected, subsidized, and otherwise favorably treated to become a symbol of progress in which few of their fellow citizens can share. A few islands of privilege in a sea of poverty are nonetheless a poor indicator of economic development. Genuine economic progress must be broadly based, usually requiring a radical reorientation in government policy toward much larger investments in rural welfare.

To a large extent, this means a substantial increase in public investments in the education, health, and practical agricultural knowledge of village people and in the technical personnel to make such investments effective. Particularly, the quality of present agricultural research personnel and programs needs much improvement and the achievement of a broader and more effective dissemination of research findings at the village level deserves top priority. Since a mere 1 per cent increase per year in Turkey's total agricultural output would pay for its present annual investment in the activities of its Ministry of Agriculture, far greater budgets (particularly for its extension service) appear to be warranted. These public services should give a major part of their attention to developing simple improvements in tools and practices which will raise productivity per worker without reducing present per acre inputs of labor or animals, which must in any case be maintained on small holdings. Nor, in Turkey's case at least, does it appear likely that an increased rate of net population growth in the rural areas will dissipate the resulting gains in output. If a choice must be made between maintaining the present levels of agricultural credit and improving and expanding the research and extension services offered to small holders, the latter should be given priority. However, such agricultural

credit as is extended to small holders should be closely co-ordinated with the recommendations of the extension service and might often be more effective if granted in kind (pure seeds, fertilizer, etc.) rather than in cash.

Apart from encouraging the widest possible adoption of practices which enable the peasant to produce more with his limited land resources, the extension service should also seek to find means of occupying profitably the otherwise idle time of village people. The development of village industries—such as farm tools and implements, hand-woven textiles and other handicrafts, and the simpler agricultural processing industries—recommends itself. So does the encouragement of co-operative endeavor on small-scale public works—such as village roads, schools, and local irrigation projects—with the government furnishing only the materials and technical assistance. Such projects have the advantage of low capital requirements, which with further economic progress will involve no important liquidation loss, while meanwhile improving the levels of living and working habits of otherwise underemployed villagers. At the same time, they can arouse in the villages the spirit of community self-help which, while now sadly lacking, is a cornerstone of general progress anywhere.

On the marketing side, Turkey needs to make more public agricultural investment in its commodity standardization and inspection program. It also needs to develop satisfactory current agricultural marketing and price statistics, agricultural outlook information, and research and extension in farm marketing and prices—basic public services which are essential if Turkish peasants and private middlemen are to be integrated into an efficient and well-organized national economy without continued centralized dominance and control of agricultural markets by the government itself. Even the large-scale agricultural sales cooperatives virtually owe their existence to the government, which has maintained rigorous control over their management and finances. The development of more democratic farmer co-operatives at the local level by an expanded extension service would appear to be highly desirable on both economic and social grounds. Finally, there is a need for a continuing program of industrialization in which the simpler agricultural processing industries, both co-operative and private, play a larger role than they have done in the past.

Upon the basis of Turkey's experience, I may sum up in a few words my conclusions on desirable directions for agricultural development policy in underdeveloped countries. In general, more agricultural investment should be allocated to people (intangibles) than to things (tangibles) but, insofar as it is allocated to things, it should usually emphasize the small and inexpensive rather than the large and spectacular. Simple

and obvious though such conclusions may appear to be, they are almost universally ignored by underdeveloped countries. However, in so doing, underdeveloped countries confuse the symbols with the substance of the industrial nations of the world. Important though symbols may be in sparking a spirit of progress, their continued overemphasis can only mean the substitution of recurrent boom-and-bust for the slow-but-sure. Conservative that I am, I would strongly recommend to such countries the latter course.

DISCUSSION

Everett E. Hagen: These two stimulating papers bracket a wide range of problems in economic development. To hold my comments to brief compass I shall limit myself to two topics: the implications of the two papers concerning general criteria for the allocation of investment in economic development, and some aspects of the specific model presented by Professor Chenery.

From the titles of the papers and from the fact that Professor Chenery's paper stresses the development of industry and Professor Nicholls' that of agriculture, it might seem that the two papers are in conflict concerning the question of emphasis on industry versus that on agriculture in the process of growth. In fact they are not—or, if they are, it is because of a difference between them relating to another issue to be discussed below. Professor Nicholls' paper does not deal with agricultural development versus industrialization; it deals with choice between two methods of developing agriculture. On the other hand, while Chenery states that he is concerned mainly with selection among manufacturing and processing industries, he really presents a method of selection among all sectors of the economy without prejudice to the degree to which agriculture on the one hand or industry on the other will be indicated by the analysis.

Further, there is no issue between them concerning linear programing versus partial or marginal analysis as the best tool for determining the allocation of investment which will maximize the increase in national income. There is little question that for such analysis linear programing is the superior tool. There is no issue here—except perhaps between the enlightened and the unenlightened. Linear programing can deal with the composition of output, price relationships, foreign exchange relationships, and alternative production methods far better than can partial analysis. These advantages result from the nature of economic development; namely, that the economy is changing, not marginally, but in all parts at once and in some parts by large increments or large structural changes. Change in each part of the economy affects other parts, and none can be analyzed without simultaneously analyzing all.

However, this is not a principle which Mr. Nicholls disputes I think that there is an implicit issue dividing the two papers, but it is not this. It is rather the issue of what criteria should govern the selection of economic sectors for development and of development methods.

Chenery discusses only one criterion: "to secure the greatest increase in . . . income (total or per capita) . . . in the long run," or, what amounts to the same thing, to minimize the inputs required for a given increase in output. But Nicholls, after tipping his hat with a properly respectful gesture to the principle of maximization of income, spends his energies discussing two other criteria.

One of these is the distribution of the economic benefits of development. He refers, not in a simple way to the distribution among income size groups, but to the distribution among sectors of the economy. His concern is valid. The criterion is sound. The benefits of industrialization will for many years reach only a limited group.

Introduction of new industry at a rate sufficient to give employment to 1 per cent of the labor force per year is an extremely rapid rate of industrial expansion. Over a period of a decade, even this rate of industrialization will benefit directly only approximately 10 per cent of the population if indeed the available human skills and motivations are such that in the short run it benefits anyone, which it may not. The agricultural population from which the new industrial workers are drawn will benefit only insofar as reduction of underemployment increases per capita income, or insofar as the industrial workers contribute to family income back in their home villages.[1] In economies in which two-thirds to three-fifths of the population is dependent on agriculture, this is not enough. It is quite possible, and even probable, that in most predominantly peasant societies a government cannot remain in power for a dozen years by democratic means unless its development program gives direct widespread benefits to the peasant population.

It is worth noting that agricultural development may be desirable for a quite different, purely economic reason; namely, to provide a market for industrial output. The extent to which any given increase in agricultural income will increase the demand for industrial products can be estimated by a linear programing model. It is the social rather than the purely economic benefits of agricultural development with which a linear programing model cannot cope adequately.[2]

A third criterion, with one aspect of which Nicholls also deals, is the social costs of the increase in aggregate output. He discussed the displacement of peasant operators by the mechanization of agriculture. The social costs involved in rapid industrialization are less simple to portray but nonetheless real. Obviously, a development program must not be abandoned merely because it involves such social disruption. Otherwise there will be no development. Any economic change involves social change, and social change involves social cost. But the social costs must not therefore be ignored. The costs involved in one program differ in amount from those in another, and even

[1] J. H. Adler noted in discussion from the floor that industrialization will itself benefit the agricultural population in some economies by increasing the demand for the type of food or other agricultural product produced in peasant farming and thereby raising the price of those products. This qualification is of course entirely appropriate. Adler noted that in this case there is often a tendency for the government to restrict the rise in price of agricultural products because of its interest in protecting urban workers from the increase in living costs.

[2] In comment from the floor, Professor T. C. Schelling suggested that a linear programing model can explore the benefits of increasing income throughout agriculture by dividing labor into several groups, one of which is agricultural labor, so that the model will show the demand for agricultural labor. However, if at the completion of the analysis there is still surplus agricultural labor, so that the shadow price of labor is still zero, a linear programing model will indicate nothing whatever about the desirability of emphasizing agriculture rather than industry in a development program. This is the deficiency which I have in mind.

though they can be measured only imperfectly they should be taken into account in determining the optimum allocation of effort.

Linear programing disregards these two criteria. It does not follow that linear programing must be rejected. It follows merely that the answers given by even a perfect linear programing model are only partial answers, and that even though the three criteria are only imperfectly commensurable, all must be taken into account.

So much for the general implications of the two papers concerning criteria for investment allocation. Now, a few comments concerning the specific development model presented in Chenery's paper.

The virtues of the linear programing process, even with regard to the one criterion of maximizing aggregate income, do not necessarily inhere in any given linear programing model. The simpler and computationally more manageable a model, the greater is apt to be the margin of error in the estimates it yields.

Professor Chenery's model illustrates this point. It is after all a very limited model. For ease of computation it contains only fourteen sectors; aggregation to this point certainly blunts the edge of the tool. Further, the model assumes fixed production functions. Variation in the ratio of labor to capital is accomplished only by choice from among different products. But one of the considerations which may be of primary importance in the development of many economies in which underemployed labor is present on a large scale is the question which among alternative methods of producing a given good will yield the greatest total employment or the greatest aggregate income. Again, the model makes only crude allowance for capital durability. It assumes, that is, that if one capital good costs three times as much as another, it constitutes three times as costly an input in production. It does not take account of the fact that the more expensive capital item may endure six times as long, and thus constitutes roughly only one-half as costly an input in the production process. This, too, is an important omission. For in an economy short of capital, as elsewhere, the question of the roundaboutness of production, the period of gestation, the appropriate rate of discount of future income is of first-rate importance in planning economic development Fourth, Chenery's model does not take into account the relative feasibility of alternative development programs. It assumes that management ability, technical knowledge, skills, and motivations will be as available for one type of project as for another. In fact, they may not. Finally the model makes no allowance for increase in productivity in specific production processes, though it makes allowance for increase in productivity for the economy as a whole through the utilization of previously unutilized labor. Yet almost by definition the process of economic development must include improvements in productivity in specific production processes.

But even though the model is less informative than otherwise because of these restricted features, this fact does not imply any criticism whatever either of linear programing models in general or of Chenery's model in particular. This is true for three reasons:

1. Each of the five limitations indicated is due either to deliberate simplification for purposes of easier presentation or to the absence of the data needed to expand the model. In all of these five respects a linear programing model can be made more realistic if the occasion demands and the data exist. The only other factor hindering the elaboration of the model is the resulting computational demands, and these are easily handled on present high-speed computors. Each type of missing information—knowledge of alternative production functions, of capital durability, of human bottlenecks, and of prospective increases in productivity—can be used at least as effectively in a linear programing model as in a "partial analysis."

2. Certain aspects of Chenery's model which are inappropriate to many countries are probably appropriate to Southern Italy. For example, in Italy managerial and technical talent and motivation may be available for almost all projects (given only top-level impetus to the total development program).

3. Finally, it seems very probable that even a rather simple linear programing model does not in general mislead because of its simplicity—that is, does not give worse results than partial analysis--but on the contrary provides valuable aid not otherwise attainable. It is worth while to remember Friedman's well-known article noting that the test of an analytical model is not the realism of its assumptions but the predictive value of the conclusions drawn from it.

Chenery has constructed a structure with imagination and a high order of craftsmanship. Its construction has given a demonstration not available previously of the power of a linear programing model in a practical situation and should be a stimulus to advance in this field. It will be recognized, I think, as a modest but nevertheless appreciable contribution to the advance of economic science.

WILFRED MALENBAUM: These two excellent papers use what are obviously different techniques in reaching decisions on patterns of investment in development programs. Professor Chenery's results come from a general equilibrium analysis in which account is taken of the interdependence of the "individual" sectors of the economy. A decision with respect to investment in industry - the sector upon which he focuses in this paper—depends upon resource availabilities and complementary investment requirements in all sectors. The analysis requires a significant amount of information, both on intersectoral flows in the economy and on the capital and labor requirements for expanded domestic output (capacity) in each sector. Comparison of some of his results with those which might be obtained by partial, sectoral analysis points up, he feels, the need for such an over-all approach.

Professor Nicholls simply asserts the need for agricultural investment in the development program of underdeveloped countries. Within agriculture, he stresses the importance of direct attention in the development program to the plight of the smaller, poorer, more underemployed agriculturist. Steps must be taken to improve his efficiency and to provide him, more or less *in situ*, with supplementary nonagricultural employment opportunities, both

of an industrial and public utilities nature. Nicholls' analysis of Turkish agricultural development activity in the recent past makes clear that the government program has not begun to meet the problems of the peasantry which constitutes 65-75 per cent of the population. Nevertheless, Nicholls' basic "explanation" for the need to concentrate directly upon this subsector of agriculture remains his insistence "that agriculture and its major subsectors must share in any real gains in per capita national income if we are to consider the claims of successful economic development valid." There is no demonstration that observed gains in per capita national income, if not shared by important sectors of the economy, are bound to prove transient and illusory. Nor is there any refutation of the proposition that real gains in per capita national income from a development program will somehow be shared by component sectors simply because of the structural interdependence of the economy.

This said, I hasten to associate myself fully with Professor Nicholls' recommendations. On the basis of my own observations and study in underdeveloped areas, both with and without "population problems," I sympathize with Nicholls' feelings that there is need to concentrate directly upon improving the economic well-being of the large rural populations. Nevertheless, it would be of great value to find in the structural interrelationships of (at least some) underdeveloped economies a more satisfactory rationale of the need for such direct action—and some measures of the relative importance to be given this type of investment in the total development program. For this, Chenery's work on general equilibrium solutions is clearly of great importance. There is no necessary inconsistency between the Chenery results and the Nicholls suggestions for emphasis in investment patterns. Chenery confines his final conclusion to the need for over-all analysis in planning industrial development. (By their very nature, however, his results also provide appropriate levels for agricultural and other nonindustrial investment.) He also indicates that investment allocations might be somewhat greater in the nonindustrial sectors of economies like that of Turkey where the marginal capital requirements in agriculture, for example, appear to be relatively much lower than in Italy.

The general model necessary for Turkey (as for India and many other underdeveloped areas) would be quite different from the one used by Chenery. In particular, the "one-way interconnectedness" of the economy which he discovers in the Italian data would, I think, have but limited relevance in these other countries. The material for Italy suggests that as per capita income increases (its distribution notwithstanding, presumably) the proportion of income spent on manufactured consumers' goods may be expected to increase. Other demands are derived from the demand for these goods. "The justification for investment in 'social overhead' facilities and in much of primary production" stems from this dependence. It is precisely the absence of evidence of such derived effects in important sectors of the economy of Turkey which provides the case for direct investment in the small-scale agricultural areas. Expansions in per capita national income arising from industrial growth or from the mechanization of a small component of agri-

cultural output do not seem to be transmitted to other important parts of the economy. For whatever reasons, consumption and production responses do not occur or are too limited in magnitude.

I must admit some uneasiness about a model of growth based upon such one-way interdependence and the simultaneous recognition of significant structural disequilibrium in the use of factors of production. Is not the existence of large underemployment in the rural sector testimony of the lack of such interdependence—in the past, if not at present? I presume that the two to three million of additional nonagricultural employment that will be provided in Chenery's investment plans are of a magnitude which will, over the decade, absorb not only the net growth in employables but also the currently underutilized labor supply. Perhaps this will indeed occur. I would feel much happier if this solution were not so apparently out of line with what has occurred in Italy in the past.

In sum, the general case for the use of the over-all approach to the determination of investment allocations is sound. Chenery's model may provide useful answers for Italy. Its extension to other underdeveloped areas requires much more knowledge about the appropriate pattern of sectoral interdependences than is yet in hand. Pending such knowledge, there is much to be said for development programs which seek to assure Nicholls' sharing of growth in per capita incomes by direct concentration upon those sectors of the economy which seem to lag.

ECONOMIC DEVELOPMENT: CASE STUDIES

COMPARATIVE ECONOMIC DEVELOPMENT: CANADA AND THE UNITED STATES

By John H. Young
Yale University

Comparisons are odious, whether involving individuals or nations, and in presenting some tentative results of a comparison which I am now making of the Canadian and American economies to a gathering containing nationals of both countries, I am aware of the delicacy of my position. It would be easy to concentrate on technical questions or to give a glowing account of the success stories of the two economies and thereby avoid controversial issues, but since it seems to me important to bring into sharp focus some of the basic characteristics of the Canadian economy, I am going to speak somewhat more frankly than might seem appropriate at this time and place. As anyone familiar with the two economies knows, the United States has enjoyed and does enjoy a substantial advantage over Canada in terms of what used to be called economic welfare. Many of us would not spend much time studying economics if we did not think that economic welfare, even if only measurable in a rough way, was of some importance. On the other hand, all of us—and here we would have the support of eminent economists from Adam Smith to Sir Dennis Robertson—would be prepared to argue that some things may be more important than opulence. Perhaps if we could broaden our concept of welfare to include political, legal, religious, and other aspects of well-being, a comparison between the United States and Canada might yield a different answer.

If we restrict ourselves to economic considerations, however, the answer is fairly plain. One hundred and thirty-six years ago a Scottish clergyman who was traveling down the St. Lawrence and had spent the night in Prescott on the Canadian side of the river, had occasion to cross over to Ogdensburg on the American side, and being struck by all the activity he saw there, remarked that "the contrast of apathy and inexertion on the one side of the river, with bustle and business on the other, cannot but be mortifying to one of genuine national feelings." He was not the first to observe a difference in the Canadian and American economies and certainly not the last. I cannot pretend to any extensive knowledge of the history of either country, but even my cursory reading has revealed that in almost every decade since the beginning of

the nineteenth century, one does not have to search far to find observers making an unfavorable comparison between the economic performance of Canada and that of the United States. It is true, that as the decades pass we hear less of apathy and inexertion and more of wage and income differentials, but the contrast remains up to the present day. Perhaps the reasons are obvious, but as Schumpeter once remarked in another connection, "Nothing is so treacherous as the obvious." The more I look into this question the more I am impressed by its complexity, and the need for a step-by-step analysis which attempts to probe beneath the surface and expose the fundamental factors at work. Given the limitation of time and space, I am going to restrict myself to a preliminary discussion of some of the consequences for the Canadian economy of two of the great national policies which have helped to create an independent political and economic unit in the northern part of the continent; namely, the transportation and tariff policies of the Dominion government. There are those who would echo the words of Pilate, "What I have written I have written," and argue that there is no point in analyzing the consequences of decisions which, while once debatable, are now a more or less permanent part of the landscape. To them I can only point out that what is said here is not intended to have any direct implications for policy whatsoever, but only intended as a contribution to a better understanding of the comparative economic performance of the Canadian and American economies. Before turning to this question, I would like to sketch in outline the comparative economic growth of the two economies in order to establish the general setting.

Any starting point is arbitrary, but given the limitations of the statistical data before 1870 and the fact that the American Civil War and the Confederation of Canadian Provinces in 1867 mark a dividing line of sorts in the histories of the two countries, the period around 1870 is as good as any. Over the whole period since 1869-70 the two economies have achieved a high rate of economic growth, and the most obvious generalization which emerges from a comparison of their economic development is that their relative position is much the same today as it was over eighty years ago. The population of both countries has increased about fourfold during the period and today, as in 1870, the continental population of the United States is around eleven times that of Canada. It is more difficult to say anything precise about the rate of growth of income per capita. In the most recent Annual Report of the National Bureau of Economic Research, Solomon Fabricant remarked that the rate of expansion in income per capita of 1.9 per cent per annum, which according to Bureau estimates has been sustained by the American economy for over eight decades, would, he suspected, find

little precedent or parallel in any other age or nation. I think from what we know of the comparative position of the Canadian and American economies in 1870 and today, it would be safe to say that for the period as a whole, the difference between the rate of growth of per capita income in Canada and the United States must have been very small indeed.

This does not mean that the rates of economic growth of both countries have been equal throughout the period. We know that in the latter three decades of the nineteenth century the population and labor force of the United States grew more rapidly than that of Canada, and we also know that positions were reversed after the turn of the century with Canadian population growth higher in each decade since 1900. There are some grounds for thinking that there has been a similar divergence in the rates of growth of real national product, but much work needs to be done before we can speak with much confidence. The publication of Dr. Firestone's ambitious attempt to measure Canadian economic growth will undoubtedly stimulate a good deal of interest in this subject and future commentators will be able to be more precise.

Taking 1900 as the dividing line on the comparative rates of growth of the two economies, the early period from 1870 to 1900 is perhaps the more interesting. Prior to or during this period several fundamental decisions were made which played an important role in determining the path which would be followed by the Canadian economy. If these decisions, which involved the economic independence of the country, had gone the other way in favor of economic integration with the United States, then the course of Canadian economic development might have differed significantly. This early period, which includes what was once known as the Great Depression, is also interesting because of the different reputation it enjoys in the economic histories of the two countries. The American literature quite rightly draws attention to some of the difficulties associated with falling prices during parts of the period, but it is also recognized that these were decades of very rapid economic growth, which in a single generation brought the American economy from a position of parity with the economies of other industrial powers to a position of world leadership. In Canadian economic history on the other hand, the period 1870-1900 gets an almost uniformly bad press. Professor Brebner has suggested that "the twenty-five years following 1873 were probably the grimmest quarter century in the history of Canada."[1] The late O. D. Skelton headed his chapter on this period with the words, "The Days of Trial,"[2] while the Royal Commission on

[1] John Bartlett Brebner, *North Atlantic Triangle* (Yale University Press, 1945), p. 221.
[2] O. D. Skelton, "General Economic History," in *Canada and Its Provinces* (Toronto, 1914), Vol. 9.

Dominion-Provincial Relations, whose report and its appendices have had something of the status of textbooks in recent years, summed up the period in the following words: "The collapse of the boom in 1873 brought on the Great Depression which continued for twenty-three years. A persistent decline in prices, a sharp shrinkage in international lending and a low level of investment caused a general stagnation. The Canadian economy strongly affected by these influences virtually stood still, although there were many internal shifts and changes."[3] This is an extreme position, but while other treatments of the period, including that of Dr. Mackintosh in his monograph for the Commission, reach a more balanced conclusion, pessimism is the rule rather than the exception. I do not think that an overly pessimistic view of this period is consistent with the evidence, but it is easy to see what could lead to such an appraisal of Canadian economic development during these years. For one thing, the level of foreign trade in both money and volume terms fell after 1873 and its growth during the rest of the period was sluggish. The importance of foreign trade in nineteenth-century Canada as a source of tariff revenue as well as a factor of prosperity, and perhaps the availability of foreign trade statistics, gave this particular barometer of national well-being too great a prominence. A similar use of foreign trade statistics would have led to a pessimistic interpretation of the American experience. Not only did foreign trade fail to expand as rapidly as had been hoped, but also the decennial censuses revealed a disappointing increase in population. During the last three decades of the nineteenth century, in spite of the fact that around one and a half million immigrants were reported landing at Canadian ports, Canada failed to retain even its natural increase. The drain to the United States was a constant source of comment, particular regret being expressed for the loss of those born in Canada. It has been estimated on the basis of United States censuses of population that over one million Canadian-born moved to the United States during the period 1870-1900, while the opposite movement of American-born to Canada was hardly one-tenth as great. By 1901, about 20 per cent of living persons born in Canada were residing in the United States. This is an old story to Canadian economists and historians and so much has been written on the subject that little need be said. There is no mystery about the motives which led too migration. Both Canadian-born and immigrants to Canada were attracted by better employment opportunities and good free land, the superior attraction of the United States during this period being closely related to geographical factors as well as world conditions. The movement of the Canadian frontier was halted by the Canadian shield which

[3] *Report of the Royal Commission on Dominion-Provincial Relations* (Ottawa: King's Printer), Vol I, p. 52.

barred the way north of the Great Lakes, while the American frontier continued to move westward, south of the lakes and beyond, until as good free land became scarce in the United States the flow was diverted north again, and returning Canadians and emigrant Americans joined those from Eastern Canada and Europe who were taking up land in the Prairie Provinces of Western Canada. Other factors played a part but the lack of a rapidly moving frontier had a serious effect on the development of Eastern Canada during these years and the flow of immigration from Canada was directed not only to the American frontier but also to the industrial towns of New England and the border states. I commend this story of an area with no frontier to those Americans who feel that the debunking of the frontier school of American history has gone too far.

While performance fell far below expectations, this does not mean there was stagnation in Canada during these years. From 1870 to 1900 the population of the country increased by just over 45 per cent—a rate of increase considerably lower than the 90 per cent growth of American population during the same period but somewhat higher than the rate of growth of American population during the thirty-year period from 1920 to 1950, and not very much lower than the 60 per cent increase of Canadian population during the same period. Moreover, such rough indicators as we have of the increase of output in manufacturing, agriculture, and other sectors of the economy point to a substantial rate of growth in output.

Around the turn of the century, the combined effect of a number of changes, including the revival in the demand for Canadian exports and the gradual filling up of the American West, began to be felt, and Canada entered the period which has come to be called the "wheat boom"—a period of rapid growth which overshadows both the twenties and the recent rapid expansion as the greatest boom in Canadian history. This period of Canadian economic history has achieved something of an international reputation from Professor Viner's use of it to test the classical theory of the mechanism of adjustment and there is no need to go into details. Within thirteen years from the census of 1901 to the outbreak of the first World War, with settlers pouring into the wheat lands of the Prairie Provinces, the population of Canada increased by almost 50 per cent as compared with an increase of only 28 per cent in the United States. Rates as high as that achieved by Canada during this period were practically the rule in the United States prior to the Civil War, and it is interesting to note that in terms of both population size and rate of growth the period 1901 to 1914 in Canada is a remarkably close parallel to the period 1801 to 1814 in the United States. That Canada has not been able to maintain a pace of popula-

tion growth as rapid as that of nineteenth-century America is evidenced by the fact that in 1854 the population of the United States had reached 26.5 million, while Canadian population in 1954 is only around 15.2 million.

Once the effect of the wheat boom had been absorbed by the Canadian economy, there is considerable similarity in the path of economic development of the two countries. The data are sketchy for the twenties and it is not until the most recent period, from 1929 to the present, that we have reasonably reliable estimates of gross national product in constant prices for both countries. For the thirties, the series for both countries show only a small increase, but from 1939 to 1953 it would appear that in both countries per capita output has increased by around 60 per cent, with the population of Canada increasing by just over 30 per cent as compared with a growth of just over 20 per cent in the United States. Given a continuing inflow of immigration into Canada, which relative to population has been about six and a half times as high as the American level during the postwar period, it appears likely that Canadian growth will continue to exceed that of the United States by a substantial margin.

To sum up, in the last three decades of the nineteenth century the population of Canada increased by 45 per cent as compared with a growth of 90 per cent in the population of the United States. Since the turn of the century, on the other hand, the population of Canada has increased by 160 per cent as compared with a growth of only 100 per cent in the United States. Such cross-section studies as I have been able to make, using estimates of wages, prices, and other information, leave me with the impression that at the terminal points of these major periods of economic development—1870, 1900, and today—the ratio between income per capita in the two countries may not have changed very greatly, although there have undoubedly been fluctuations in this ratio which will be revealed when and if we obtain better information.

Such comparisons are obviously very rough and the difficulty of obtaining any accurate measure is evident from the variety of estimates of this differential which have been made in recent years. It would be interesting to discuss some of the theoretical difficulties which arise in such a comparison, as well as the problems involved in the selection of the appropriate variant of national income, the adjustment to a common definition, and the difficulties involved in collecting price data covering not only consumers' goods and services but also investment goods and services and the cost of government services. If we are to have a reasonably precise estimate of the difference in average per capita income and product which will command general agreement, a fairly considerable research project will be required, but for present purposes a cruder

measure will suffice, and I shall simply assert that from the little work I have been able to do on this question, I would regard estimates (using either Canadian or American prices) which place Canadian gross national product per capita in the range 70-75 per cent of that of the United States, as probably accurate within a few percentage points either way. Some of this difference is more apparent than real. For example, the occupational distribution of the Canadian labor force differs from that of the United States. In the postwar period, around 20 per cent of the Canadian labor force has been engaged in agriculture as opposed to 12-15 per cent in the United States. As we all know, income statistics tend to show substantially lower incomes for those engaged in agriculture, but there are some who would argue that such statistics tend to overstate urban incomes and understate farm incomes, so that at least part of the difference arising from occupational distribution may be illusory. Much the same kind of observation could be made about another factor which plays a part in the income differential. It appears that labor force participation rates among married women and teen-agers are lower in Canada and this tends to lower per capita income relative to the United States. Whatever might be said about teen-agers, we all know that there is only a statistical justification for omitting the value of housewives' services from national income, and that Pigou used the example of the fall in national dividend which results if a man marries his cook to show the arbitrary nature of such measurements. Lower participation rates for married women in Canada is incidentally an interesting piece of evidence of a difference between the two countries in what Professor Rostow has called the propensity to seek material advance. At one time the difference in the international investment position of the two countries was a factor of considerable importance, Canada being the world's largest debtor country prior to World War II, with net payments of interest and dividends equal to almost 6 per cent of national income in 1939. In recent years this has fallen to around 2 per cent, while net receipts of interest, dividends, and branch profits have totaled less than 1 per cent of US national income. Once we have stripped away differences arising from occupational distribution, the share of the population in the labor force and the international investment position of the two countries, we are still left with a hard core which appears to be of long standing.

The persistence of this income differential over a long period suggests that the factors at work are fundamental in character—perhaps even physical and climatic. Before accepting an explanation resting upon natural factors, however, we should remind ourselves that the economic development of Canada has not followed the lines dictated by "natural" economic forces. It would appear that at least two of the major Cana-

dian policies implemented during the period since 1870—transportation development and tariff protection—represent in part an interference with natural economic forces and have been widely accepted as the price to be paid for a measure of political unity and independence.

The decision to use transportation facilities as a means of unifying the country dates from at least the time of Confederation and perhaps earlier. Promises of a transportation link were made to both the Maritime Provinces and British Columbia as a condition of entry, and the Intercolonial and the Canadian Pacific Railways redeemed these promises. When offered a chance to participate in the building of the Pacific railway, the Grand Trunk, Canada's principal railway of that time, was unwilling to accept unless the transcontinental line passed south of Lake Superior. It should perhaps be pointed out that the Grand Trunk was a British company and throughout the story showed scant respect for the niceties of national boundaries. The government of that day insisted on an all-Canadian route, and Canada's first transcontinental railway, instead of joining the eastern and western portions of the country through high traffic-potential American territory, was pushed through almost a thousand miles of barren country with little immediate or even long-term prospects as a source of traffic. The same policy was at work during the next great railway building era following the turn of the century. During this period of unbounded optimism, it seemed obvious that the country needed not one but three transcontinental railways, all of which would run north of Lake Superior. The Grand Trunk again appears on the scene this time with a projected railway which would join its western subsidiary to the East by way of Chicago. Again its offer was rejected in favor of a more expensive alternative, and the National Transcontinental was built by the government from Winnipeg to Moncton on the Atlantic seaboard. The epic story of the third transcontinental railway—the Canadian Northern—deserves more than a sentence, but when it was decided that it too needed a route to the East, after a mild attempt to economize on transcontinentals by encouraging the Canadian Northern to double up, it was able to press ahead with help of guarantees from the federal government. This railway expansion was mainly financed by British investors, and in view of the fact that a substantial proportion of the capital inflow from 1901 to 1914 was used for building railways, it is easy to understand Viner's conclusion that "the borrowings during this period were in large part invested in economically unsound ventures."[4] Unfortunately for the Canadian taxpayer, the federal and provincial governments were deeply involved and when the time came to pay the piper, he had to foot the bill. Perhaps

[4] Jacob Viner, *Canada's Balance of International Indebtedness 1900-1913* (Harvard University Press, 1924), p. 305.

this was no less than just, since the government had received substantial public support for its transportation policy, although later commentators have argued that the government might have been able to drive a better bargain when it became necessary to do something about the incipient bankruptcy of the Grand Trunk, the Grand Trunk Pacific, and the Canadian Northern. It was decided that the liabilities of these railways should be assumed by a nationalized railway system—the Canadian National Railways—which took over control of all private and government railways in Canada, with the exception of the properties of the Canadian Pacific Railway. With an unco-ordinated group of railways, often with duplicate facilities, and with a capital structure which bore no relation to potential earning capacity, the Canadian National Railways was unable to meet its fixed charges, and in each year from 1923 to 1952, with the exception of two years in the twenties and the war years, the nationalized railway system showed a deficit. These deficits were at one time rightly regarded as a pretty serious business for the economy as a whole, but in general it can be said that either the deficits or the adjustments designed to put the capital position of the Canadian National Railways on a more realistic basis are a good deal less awe-inspiring today. One would expect to find some reflection of these financial difficulties in the physical statistics of Canada's railways, and it does appear that in terms of traffic output per employee the US railways make a better showing. How far this is due to the inadequacy of the measure, how far it can be attributed to the enthusiastic railway expansion of the past which has contributed to lower traffic density on the Canadian railways, and how far it is related to other factors is something on which I hope to have more to say at a later date. When reference is made to the transportation difficulties under which the Canadian economy operates, it must be remembered that while some of these can be attributed to natural factors, at least in part they are a reflection of an economic policy which accepted higher transportation costs in pursuit of other ends.

It is more difficult to assess the consequences for Canadian economic development of the policy of tariff protection. Broadly speaking, Canada at Confederation was faced with a choice of one of three alternatives: first, the retention of a low revenue tariff in the face of the high tariff maintained by the United States; second, the promotion of freer trade between the United States and Canada by prevailing upon the United States to agree to reciprocal tariff reductions; and, third, the choice which was made when attempts to obtain reciprocal tariff reductions proved fruitless: the adoption of a policy of tariff protection for Canadian manufacturing industries. This policy has been a continuing element in Canadian economic development since 1879, although through-

out the latter decades of the nineteenth century, and indeed up to the rejection of the reciprocity proposals of 1911, large-scale reciprocal reductions of the Canadian and American tariffs were always regarded as a possible alternative. Given these three possibilities, it may appear idle to speculate on what would have been the consequence of accepting some other course of action than the one actually adopted, but in order to decide whether the apparent economic costs are or are not real ones, some such attempt must be made.

Following the first course of maintaining a low revenue tariff while the United States retained a high tariff was an unattractive alternative as compared with some measure of continental free trade. One is bound to feel some sympathy for Canadian manufacturers of the 1870's who were quite prepared to meet American competition under free trade conditions but who argued that if the American manufacturer were accorded protection in his market, it was only just that the Canadian manufacturer should receive protection in his. At the same time it is well known that in the absence of rather special conditions, there is a presumption that, regardless of the tariff policies followed by other countries, any one country merely injures itself further by raising its own tariff. Are there any grounds for thinking that the special conditions required if a tariff is to provide a net economic benefit have been present in Canada? In the most detailed study of Canadian tariff policy presently available, it is held "that if Canada had kept her tariff at revenue levels without receiving reciprocal concessions in foreign markets the results would not have been advantageous as compared with existing levels of national income enjoyed."[5] It should be possible to justify this contention by reference to international trade theory, and certainly no one can complain that students of international trade have not devoted considerable ingenuity in recent years to discovering possible advantages for protection. Quite the contrary. Yet a search through this literature fails to bring to light any good argument for Canadian protection if we restrict ourselves, as we should, to long-run economic considerations. The long-run elasticities are almost certainly high enough to rule out the possibility of gaining by an "optimum" tariff any higher than a revenue level. Bargaining tariffs have a tendency to build up vested interests which prevent any easy reversal of policy, and the Canadian tariff has been no exception. Infant industries should be nurtured, but if their problem is their inability to compete with American industries enjoying the advantage of a large domestic market, then it is a fair bet that they will tend to remain infants. It is true that capital and enterprise can be attracted by a tariff, and the establishment

[5] Orville John McDiarmid, *Commercial Policy in the Canadian Economy* (Harvard University Press), p. 385.

of American branch plants in Canada has been one spectacular product of the Canadian tariff, but the flow of capital and enterprise into the unprotected sector of the economy is discouraged, and there does not appear to be any way in which a balance could be struck in deciding whether Canada has achieved a greater or smaller inflow of capital and enterprise by having a tariff. Ohlin—who discussed the Canadian case specifically—reached no definite conclusion. But if capital and enterprise have been attracted, this would imply that the return to these factors has been increased over what it would have been in the absence of a tariff. This in turn must have lowered the returns to either one or both of the other factors: land and labor. Since Canada has not had and does not have a wealthy landlord class which can be exploited, the burden then necessarily falls on the ordinary farmer or on the ordinary employee or on both. Those who argue that the tariff has had the effect of reducing migration to the United States are in effect arguing that increasing the disparity of income tends to discourage migration. The one good argument for Canadian protection is probably the one which has often been used rather cynically, and that is the conservation of natural resources. Given our inability to handle conservation problems at all neatly, since they involve uncertainties about future technological possibilities and, like other types of saving, intergeneration comparisons of utility, it is doubtful if anything useful can be said about this proposition, although it may have more validity than more popular arguments.

If a revenue tariff might have been less injurious than protection, clearly continental free trade offered even more favorable prospects. Professor Dales has shown that Ontario and Quebec—the two provinces which are said to have benefited from the tariff—have the locational attributes of industrial regions, and if there could have been a measure of certainty on the continuance of some form of commercial union, it appears not unlikely that there would have been a considerable movement of American industry to these areas. Under these circumstances, we might have had Professor Seymour Harris scolding Canadians instead of Southerners for attracting industry by unfair means and books might have been written entitled, "Why Industry Moves North." As things turned out, a view gradually developed that the economic links forged by the tariff were necessary if a measure of political unity and independence were to be achieved. It is true that this view was less popular in the Maritimes and the Western provinces than in the provinces which thought they had benefited from the tariff; but there was a sense in which the national policy lived up to its name.

The consequences of the Canadian tariff can be observed in Canadian

manufacturing today. There are a number of protected manufacturing industries which although paying a level of wages 15-20 per cent lower than that prevailing in the United States appear to be unable to quote competitive prices. Canadian manufactures in these industries have traditionally argued that apart from the fact that their materials, parts, etc., are subject to a tariff, the main reason for their relatively high costs is that they are producing for a market one-tenth to one-fifteenth the size of the American market. I have been attempting to test this proposition through the use of data on labor productivity in different types of Canadian industry and by gathering information from American and Canadian manufacturing firms carrying on operations in both countries. While I am not yet in a position to reach any firm conclusion, the results achieved so far give some support to this point of view. This is of some interest to economists in both countries, since it tells us something about the importance to the American economy of the size of the American market. The late Professor Allyn Young, in his famous *Economic Journal* article on "Increasing Returns and Economic Progress," suggested that "in certain industries, although by no means in all, production methods are economical and profitable in America which would not be profitable elsewhere. The importance of coal and iron and other natural resources needs no comment. Taking a country's economic endowment as given, however, the most important single factor in determining the effectiveness of its industry appears to be the size of the market." In comparing Canadian-American industry, I have found some evidence which would suggest that at least the first part of Young's observation is quite valid. American firms with American management and what in many cases is in effect the equivalent of an American working force, producing for a market which in many cases has American tastes, find that highly mechanized production methods which are economical and profitable in America are not profitable in Canada. There is one disturbing factor which may weaken this evidence. The level of wages is lower in Canada and sometimes, because of the tariff, the cost of machinery is higher. What about the possibility that substitution has an important effect? As everyone knows, marginalism never comes off very well in crude empirical studies. Here and there one finds a businessman who has either remembered something from his introductory courses in economics, or pays more attention to relative factor prices than his fellows, or has more possibility of substitution in his industry (in the language of activity analysis has a greater choice of activities) and he will report that relative factor prices have influenced his decision. But they are few and far between, and while I would be prepared to agree with those who argue that more substitution goes on

than reaches the consciousness of businessmen, if almost all one hears by way of explanation of different technology involves the scale of the market, this begins to carry some weight.

Bearing in mind the fact that limitations on the scale of the market facing many manufacturing industries in Canada are not natural phenomenon but rather the consequence of Canadian and American tariff policies, it would be interesting to know how important this factor is in lowering per capita income in Canada. I do not know the answer and I do not expect to know the answer with any precision, although I think something useful can be accomplished by further work on this question. It may turn out to be of considerable importance, although it must be remembered that the scale of the market is only of prime importance in manufacturing, and that in spite of the implicit assumption which seems to be made in many discussions of economic questions there are a few people employed outside manufacturing. In Canada in the postwar years around one-quarter of the labor force has been employed in manufacturing and a somewhat higher fraction of national income has originated in that sector. Since a portion of Canadian manufacturing is producing for the North American or world market while another portion is relatively unaffected by the limited size of the Canadian market, we are talking about a piece of the economy which is only a fraction of a fraction. As a result, the impact will be considerably lessened when measured against the economy as a whole.

I have concentrated on the transportation and tariff policies of the Dominion government, not because I think that these are the only factors in establishing and maintaining an income differential, nor even the most important ones, but simply because there is a limit to what can be said in one short paper. There are a number of other issues which might have been discussed. Differences in sectors of the economy outside manufacturing and transportation may give important clues in unraveling the puzzle. The part played by population also raises a number of interesting questions, which have come in for considerable discussion in recent years but on which the last word has not yet been said. Finally, there is that fascinating generalization that Canadians are in some sense less enthusiastic in their pursuit of economic ends than their neighbors—a proposition which is not easily testable but which may yet be attacked by an orderly collection of evidence.

We have seen that in at least two respects the policies followed by the Canadian people have had the effect of interfering with the free play of what might be called the natural economic forces, and it has been argued that this interference has had the effect of lowering per capita income in Canada. This does not mean that if viewed in a framework broader than that provided by economics, these policies were, and are,

wrong. The idea of a country extending from sea to sea which would have an independent existence and not be simply a northern extension of the United States came to be widely accepted as a worth-while goal in Canada, and it is often argued that these policies have made an important contribution to this goal. The result has been an experiment which is unique. A string of communities, stretching in a broken ribbon across a continent and in the case of two-thirds of the population with no language barrier separating them from nearby communities across the border, has developed into a national entity with a life of its own. This process has involved certain economic costs, but there is every reason to suppose that those who launched this experiment would not be displeased with the results which have been achieved.

ANGLO-AMERICAN PRODUCTIVITY DIFFERENCES: THEIR MAGNITUDE AND SOME CAUSES

By MARVIN FRANKEL[1]
University of Illinois

Differences between underdeveloped and industrialized countries in labor productivity usually are so marked that one can take their existence for granted. When, however, the contrast is between two industrialized countries, such differences are less obvious and, for any particular industry, often uncertain as to direction. Here statistical measurement serves as a useful prelude to any discussion of causes. The size and pattern of differences, together with additional information emerging as a by-product of the measurement process, are themselves indicative of the paths which explanatory hypotheses might take. Thus, though this paper is given in the main to a discussion of certain hypotheses commonly advanced in explanation of Anglo-American productivity differences and also to suggestions regarding a few others, its first section presents some statistical comparisons for the two countries and describes briefly the methods employed and the limitations of the findings.

I. *Productivity in Thirty Industries*

The table below, based on the United States *Census of Manufactures* for 1947 and the United Kingdom *Census of Production* for 1948, compares British with American labor productivity for thirty industries. The comparison is made in terms of ratios of physical output per worker and physical output per man-hour in the US to the same measures in Britain. Ratios also are given comparing size of market and size of plant. Collectively, the industries represent about 13 per cent of value-added in US manufacturing and 16 per cent of that in British (GB) manufacturing. Their selection was based solely on the amenability of census data to the purpose at hand. Product homogeneity and product classification in census reporting were principal considerations.

A variety of difficulties attend any statistical endeavor to measure industrial productivity, and the difficulties are compounded in the case of international comparisons. Both US and GB censuses pose obstacles

[1] The author expresses thanks to V. Lewis Bassie for many helpful comments on this paper, to Phyllis Barnard and Charles Z. Wilson for their able research assistance, and to the University Research Board, University of Illinois, for a grant-in-aid of the project on which this paper is based.

TABLE 1

PRODUCTIVITY IN THIRTY BRITISH AND AMERICAN MANUFACTURING INDUSTRIES*

Industry	Physical Output per Worker† US/GB Ratio	Physical Output per Man-hour‡ US/GB Ratio	Size of Market (Physical Output) US/GB Ratio	Size of Establishment	
				By Number Employees US/GB Ratio	By Output US/GB Ratio
Tin containers...	4.96	4.97	9.49	1.04	5.43
Cardboard containers.... .	4.20	4.24	11.75	.94	*4.59*
Pig iron	4.17	4.91	5.78	80	3.42

Manufactured ice	.75	.69	41.27	.59	.46

* For the US, the figures relate to establishments employing ten or more persons For Great Britain they cover establishments employing eleven or more persons

† The term "worker" includes all employees—production workers (operatives) plus administrative, technical, and clerical workers.

‡ "Man-hours" refer to the man-hours of all employees, not just production workers (operatives) To obtain man hours on this basis, adjustments to the data additional to those made in the computation of output per worker are required. These adjustments are necessarily somewhat arbitrary and subject the output per man-hour figures to a slightly greater margin of error than applies to the output per worker figures.

§ All figures are rough approximations. Because of methods of census classification and reporting, certain figures are subject to a larger margin of error than others. Such figures are italicized.

SOURCES: The figures are derived from data in the U.S. Department of Commerce, *Census of Manufacturers: 1947*, Volumes I and II (Washington: U.S. Government Printing Office, 1949), the Board of Trade, *Final Report on the Census of Production for 1948*, selected volumes (London: HMSO, 1951, 1952, and 1953), and the *Ministry of Labour Gazette*, Volumes LVI, No. 10, LVII, No. 3 (London: HMSO, 1948 and 1949).

to the computation of matching product and employment categories. Both permit but imperfect determination of man-hours worked. Both leave unanswered many questions with respect to product classification and definition; in no instance, not excepting pig iron, brick, and cement, is the product truly homogeneous; yet without the knowledge of specialists one cannot be certain how the findings are thereby affected.

Comparative treatment of the two censuses gives rise to two further problems of major importance for physical productivity ratios. One of these concerns the lack of comparability in product structures between the two countries. Within many product complexes, for example, the British produce subproducts in different proportions from the Americans. This circumstance, together with lack of a uniform terminology and differences in methods of product classification, renders impossible in most instances a comparison of identical products. The most to be hoped for is a "reasonable" similarity in the things being compared. What is meant by reasonable is, of course, an open question. Even were it possible, it would not necessarily be best always to delimit the comparison to identical products or to adjust the data to eliminate the influences of product variety. For certain industries, differences between the two countries in the kinds and degrees of differentiation of both intermediate and end products have a good deal to do with differences in production methods and per worker output levels. In assessing the significance of this factor, one has need of productivity figures that reflect its effects.

The second problem relates to differences between the two countries in the degree to which various of the industries are vertically integrated. It relates also to differences in methods of reporting by the censuses. In the US, for example, establishments brewing beer also bottle it while in Britain bottling is done by establishments classified to a separate industry. Thus though both censuses report output in numbers of barrels, US output is subjected to additional processing which the figures do not reflect. In this instance a corrective adjustment is possible, but for most industries, it is by no means clear from the censuses whether significant differences in the degree of integration or in the methods of census reporting exist. Even where the nature of any difference is known, adjustment for it may be quite impractical. The virtues of physical productivity ratios—their seeming comparison of like with like and their freedom from the influence of fluctuating prices —are lessened by problems such as these.

Because of occasional variations in methods of reporting and details given by the censuses of both countries, complete uniformity from product to product in computational procedure was not possible. For

Britain, customary procedure, in barest outline, was to begin with sales figures together with corresponding physical quantities for a given product and then to adjust them for that fraction of sales made by establishments classified to other trades and for inventory changes during the year. A matching employment figure was then obtained by adjustments, where necessary, based on the value of output figure. Information on man-hours worked, drawn from the *Ministry of Labor Gazette,* supplemented the employment figures. For the US it was usually necessary to begin with total shipments of a product, and then to adjust the figures for shipments by establishments classified to other trades and for inventory changes during the year. The census gives total man-hours directly. (See footnote ‡ of the table on this point.) Adjustments to this figure to eliminate the influence upon it of production by an industry of certain secondary products yielded matching quantity and man-hour data.[3]

The statistical findings in the table represent at best a rough approximation of the facts. The limitations enumerated above—as well as the more commonly recognized ones attaching to all productivity comparisons, whether between countries or over time—must be kept in mind. Fortunately for what follows, we need not rely on the exactness of the figures.

Our physical productivity ratios range from a high of about five in the manufacture of tin containers to a low of about seven-tenths in the manufacture of ice. From among all of the ratios, only this latter one and those for beet sugar and cured fish (output per worker only) show an advantage for Britain. No obvious explanation of the ranking of the ratios suggests itself. Several industries employing comparatively roundabout and highly automatic methods possess high ones; e.g., cardboard containers, cigarettes, tin containers. At the other extreme, the ratios for cured fish, paint brushes, and bicycles—all relatively labor-intensive industries—rank fairly low. But the tendency is not clear cut. Rubber tires, boots and shoes, and margarine make use of highly indirect production methods, but the US/GB productivity ratios are not correspondingly high. More worthy of note is the fact that the US advantage, rather than being limited to any few products or production

[3] As noted in the text, a consideration in selecting industries for comparison was product homogeneity. For that reason it sometimes proved feasible in arriving at an output figure simply to aggregate the quantities given for the various subproducts of a product group An alternative procedure, employed in instances of more complex product structure, was to select a "typical" subproduct common to both countries and to adjust the other subproducts to a comparable quantity base through use of an implied price for the typical subproduct. Here the quantity of any subproduct is given by the formula $\Sigma v_i/p_A$ where v_i is the value of output of any subproduct and p_A the price of a unit of the typical subproduct. This procedure was used only in instances when the typical subproduct constituted a major fraction of the total value of the product complex.

methods, is more or less pervasive through technical processes and product types.

So large a margin as that which, on the average, favors the US cannot have developed over a few years or even over a decade or two. It must be the outcome of a lengthy process of differential economic change between the two countries. If the hypothesis is accepted that the relationship was reversed, with GB productivity the higher until perhaps the early part of the nineteenth century—in what degree remains quite uncertain—then the inception of Britain's relative disadvantage belongs back a hundred or more years.

Of interest are some comparisons of productivity for prewar years. As might be expected, they evidence a marked advantage for the US. Basing his calculations on census data for the 1935-39 period, Rostas found for some thirty-one manufacturing industries an average US/GB ratio of output per man-hour of 2.8. He found, further, that the US advantage was not confined to the manufacturing sector but extended with even greater force to mining, public utilities and communications, and transport while significant but less marked disparities prevailed in building and construction, distribution and services, and government.[3] Estimates utilizing supplementary materials confirm these conclusions. (See P. Barna, *Oxford Institute of Statistics Bulletin*, July, 1946.)

Comparisons for yet earlier periods support the impression yielded by those for later ones. Taussig has provided information on physical output per worker in 1907-09 for several industries.[4] His US/GB ratios are 2.2 for pig iron, 2.1 for steel, 2.9 for tinplate, 2.0 for cement, 1.7-2.0 for sugar refining, 1.5 for flour milling, and 1.2 for ice. Another set of data, based on money values and of considerably greater scope, are available for the same period.[5] Here the average of ratios for thirteen industry groups is 2.26. In light of the available statistics, there can be little doubt not only that US labor productivity greatly exceeds that of Britain but also that the US advantage extends back well into the last century. The sources drawn upon and methods of computation employed differed for each of the several sets of data referred to. For this reason no attempt should be made to compare them directly or to compute from them, for particular industries or economic sectors, rates of change in productivity differences over time.

II. *Explanatory Hypotheses*

International productivity comparisons sometimes are regarded as indicators of the relative effectiveness with which countries allocate and utilize their resources. At stake whenever they are so regarded is the particular definition of efficiency being used. Output per man or man-hour measurements ignore capital inputs which are equally with labor a real cost, albeit less easily measured. They ignore the fact that differing demand structures might require somewhat different types and qualities of product. They neglect the fact that differing resource conditions sometimes require different techniques of material handling and fabrication. It is conceivable, in some instances certain, that conditions in two countries so diverge as to call for quite different methods and organization of work. Where therefore one's concern is with the effectiveness with which resources are being used, what is needed are not man-hour output figures or even data covering direct and indirect expenses reduced to some unit of real cost. Ideally, what is needed is some notion of optimum resource use and the degree to which practice falls short of attaining it.

These considerations render improper use of the US/GB ratios as measures of the success or failure of either country in realizing economic utilization of its resources or in achieving best practice in its production methods. Nevertheless, it is well to remember that just as increases in productivity over time within a country signal reductions in real unit costs, though not necessarily in the same degree as productivity increases, so differences in productivity between countries generally indicate differences in real unit costs. A commonly espoused objective of economic policy is the continued increase over the years in productivity levels. Inquiries into the causes of US/GB differences may yield clues on how best to further this objective.

Resource Differences as a Cause of Productivity Differences. Resource conditions may affect productivity levels in a number of ways. An obvious direct effect is on the level of productivity in the extraction industries. Coal and iron ore are familiar examples. Supplies of these minerals are more accessible in the US than in Britain, permitting shallower mines and a larger proportion of opencast mining. These facts go far to explain the higher US/GB man-hour output ratios for iron ore and for coal. Resource conditions also act indirectly on productivity in mining by fixing limits to the degree and kind of mechanization permissible. Much modern cutting and conveying equipment is unsuited to British coal mines, where shafts are deep and seams thin.

The impact on the resource-using industries, exerting itself in many directions, may be equally great. American productivity in the manu-

facture of paper and paperboard containers and in the packaging process itself benefits considerably from abundant supplies of good quality paper and board.[6] Not only do the raw materials lend themselves to mechanized methods of processing more readily than do those imported by Britain, but their lower cost relative to labor and machinery costs conduces to employment of material-using, machinery-using laborsaving methods.[7] In steel-making, the much lower phosphorous content and somewhat lower sulphur content of the basic iron available to US plants aids their productivity,[8] while access of US steel foundries to cheap Bentonite and high quality silica sands facilitates their use of laborsaving techniques.[9] Again, US productivity in the manufacture of shoes benefits from the better quality of leather available here than in Britain.[10] Where the raw material is a fuel, its scarcity and consequent high price is likely to restrict the development and application of various kinds of power equipment. Absence of petroleum and natural gas deposits in Britain doubtless has something to do with the extent and quality of mechanization in its industries.

One of the commonest theories accounting for America's comparatively high productivity relates to the indirect effects of the country's abundant land supply. Opportunities on the land and at the frontier during the last century, it is said, reduced the supply of labor available in industrial areas. Resulting factor price ratios conduced to mechanization which, it is claimed, is the principal determinant of labor productivity. The conventionally assumed relationship between land supply, wage rates, and intensive mechanization is not contested here. Whether mechanization is the primary factor accounting for high productivity in the US is discussed in a separate section below.

It is worth noting that some of the handicaps faced by Britain in

[6] Anglo-American Council on Productivity, *Packaging* (London and New York, 1950), pp. 23-24. (Reports by this organization which are the outcome of visits to the US by British teams of specialists will henceforth be designated Productivity Reports) The report states: "The U.S not only is a producer of basic paper and board fibres, but converts them into finished materials of outstanding quality These fine materials are the foundation of the ultimate packages and of the mechanical packaging process This relationship cannot be ignored." It notes that in the US conversion industries, "slow running, stoppages and excessive spoiling due to faulty materials are rare, while in the packaging industries higher output can be obtained . . . because of the higher degree of rigidity and consistency in the material and a consequent greater structural strength"

[7] *Loc. cit.* Resource shortages may be "induced" as well as "natural." Rostas, *op cit.*, p. 203, refers to the heavy duty on raw tobacco in Britain In face of the resulting high price, the industry, to minimize the wastage of leaf, strips a sizable proportion of it by hand and operates its stripping machines at comparatively low speeds.

[8] British Iron and Steel Federation, *The Iron and Steel Productivity Report*, p. 6. This document summarizes the productivity report published by the Anglo-American Council on Productivity.

[9] Productivity Report, *Steel Founding* (1950), p. 34.

[10] ". . . the outside cutter, applying the die to a clear surface skin, finds it necessary to spend less time moving his pattern, selecting the appropriate quality of the surface and feeling the skin for texture, weight or quality." Productivity Report, *Footwear* (1951).

the way of raw material shortages or materials of inferior quality are not attributable directly to natural conditions but are in part the outcome of British industrial and technological practice. Thus, in fabrication of tin containers, British producers must rely on the hot mill plate in general use in their country while US producers benefit in terms of cost and productivity from abundant supplies of technically superior cold-reduced tinplate. "The saving in cost is not just in the material itself but in the higher production speeds which can be attained with a consistent raw material having the appropriate qualities." (*Packaging, op. cit.,* page 19.) Similarly, the machinability of steels and cast iron used for machine tools in Britain generally is inferior to those used in the US,[11] and the surfaces of metal products often are poorer and require more finishing.[12] Instances like these tell us something about methods in the industries consuming intermediate products but little about conditions in the industries supplying those products. To assess fully the influence of resources on productivity, conditions in both groups of industries must be considered.

From the evidence it is fairly clear that resource differences contribute in many instances to productivity differences. However, resource differences seem not to suffice as a general explanation of productivity differences. As noted earlier, the US advantage is not confined to any special group of industries. It pervades the new as well as the old, the highly mechanized and standardized as well as the less technically developed, and those producing consumers' as well as producers' and durable as well as nondurable goods. The differences are not limited to the manufacturing sector, but appear to extend to others. Hence it cannot be said that they relate only to those products or processes that might be exceptionally affected by resource or similar endowment factors. It must also be remembered that technological and product requirements fix limits—occasionally narrow ones—within which modern industrial communities must work, and to this extent the scope for intrusion of the resource element as a factor affecting productivity is reduced. To the same extent, productivity differences will reflect the impact of other factors. In many instances, moreover, raw material costs are but a minor element in total fabrication costs.

Equipment Differences as a Cause of Productivity Differences. The one element which is held more frequently than any other to be mainly responsible for high productivity in the US is the extensive use of capital equipment. Indeed, high productivity and the employment of

[11] Productivity Report, *Metalworking Machine Tools* (1953), pp. 1-2.
[12] Productivity Report, *Metal Finishing* (1951). "The excellent surface condition of the metal available in the U S. . . . may be the most important factor in the comparison of American and British (polishing) practice, since this condition controls the number of stages of polishing and the effort required at each stage" (pp. 21-22). See also p. 12.

large amounts of machinery are usually regarded as inseparable. Almost without exception, the recently published Anglo-American Productivity Reports comment on the greater aid received from machines by the American worker than his British counterpart. Writing half a century earlier, the Mosely Industrial Commission (a team comprised largely of British trade-union representatives) emphasized the same point.[13] Still earlier, in the 1850's, members of another British group stressed the tendency of American manufacturers to adopt machinery wherever possible and took cognizance of its effect in many industries. In the view of one of these observers, America's pace of industrial development was attributable to "the universal application of machinery effected with a rapidity that is altogether unprecedented."[14] Without doubt, equipment differences comprise a large part of the explanation of observed productivity differences. For the present discussion, however, the relevant question is whether equipment differences, by systematically accounting for US/GB productivity differences in a range of industries, suffice as a general explanation of the latter.

For want of suitable data, the question is difficult to test. To the writer's knowledge, estimates of the quantity of capital employed industry by industry for both countries are not available. Horsepower figures provide a crude substitute measure. Such figures are not given in the 1947-48 censuses, but Rostas has taken them from censuses for earlier years.[15] His findings show for the manufacturing sector as a whole that the horsepower per worker ratio for the two countries is about 2 to 1. (These horsepower figures, along with Rostas' productivity figures, may also be used to throw some light on the question of whether equipment costs offset the laborsaving advantage possessed by the US. Since, for the manufacturing sector as a whole, the US/GB ratios of output per worker and horsepower per worker are both about 2 to 1, horsepower per unit of output is about the same for both countries. Insofar as horsepower is a measure of capital cost, it follows that lower unit labor costs are achieved in the US without any increase over Britain in unit capital costs. US productivity defined as 1/unit labor cost plus unit capital cost, while somewhat less than twice as high as UK productivity, is still substantially higher than the latter.) This 2 to

[14] *New York Industrial Exhibition: Special Report of Mr. Joseph Whitworth*, British Sessional Papers, House of Commons, 1854, XXXVI, p. 5. Observations on the unusually extensive application of machinery are found frequently both in this report and the companion report by Wallis (*Special Report of Mr. George Wallis*). See also D. L. Burn, "The Genesis of American Engineering Competition 1850-1870," *Economic History*, Vol. II, pp. 292-311.

[15] Rostas, *op. cit.*, pp. 52-54, 68-70. He gives figures for the UK for 1930 and for the US for 1929 and 1939. The UK figures are for horsepower in use and the US figures for horsepower installed.

1 ratio approximates that which he obtained for output per worker, suggesting a relationship between productivity and equipment used. But when the situation is examined industry by industry, the most one may say is that in the US productivity is greater by varying amounts and so is horsepower, with little systematic relationship between the two. US industries enjoying relatively large productivity advantages over corresponding GB industries are not regularly aided by amounts of horsepower proportionately above the average, and those with smaller productivity advantages do not always use horsepower in amounts proportionately below the average.

Unfortunately, no simple quantity index of equipment used will adequately measure its effects. Equipment differences are of a qualitative as well as a quantitative kind. Machines need not be more costly or of greater power to perform better. The very essence of an innovation is the qualitative change in technique it entails. Moreover, equipment differences usually carry with them ancillary differences—in plant layout, material flows, labor skills, and the like. In short, equipment differences reflect themselves in many dimensions other than the quantity of capital dimension. In practice there is no easy way of deciding which of these ancillary differences or what part of any one of them to associate with equipment differences, nor is there any easy way of measuring their importance. This is not to say that the relationship between productivity differences and equipment differences must be greater than the horsepower figures indicate. But these considerations suggest that it probably is more fruitful to regard differences in the quantity of capital employed as but one of several factors contributing to productivity differences rather than to seek for or expect any simple relationship between the two.

The Market-size Hypothesis. The theory that the productivity level is related to market size is a corollary of that which ties the productivity level to the quantity of capital employed. Modern methods are founded, by and large, upon the use of machinery and equipment in fairly large blocks. In face of the resulting indivisibilities and the need for a high degree of specialization in the application of mechanical and human effort, small markets constitute a handicap. Relatively large markets make for reduced costs and high productivity by facilitating an optimum division of function within the plant, within the industry, and throughout the economy. Upon this generally recognized fact are founded most of the observations which attribute Britain's low productivity to the nature of its markets. These, it is said, are too small to allow for both sufficient variety of product and at the same time its output on a basis permitting the economies of standardized mass processing.

In all but three instances—cured fish, beet sugar, and margarine—our data indicate that the US market, as measured by national output, is larger than the British market. In several instances—like paper bags, radio receiving tubes, cardboard containers—it is more than tenfold larger. But there exists no regular relationship between differences in market size and differences in productivity. Given differences in productivity sometimes are associated with much larger differences in market size, as with animal feeds and boots and shoes. At other times given differences in productivity are associated with much smaller differences in market size, as with cigarettes and wool yarn. With few exceptions, the inclusion of small establishments—those with ten or fewer employees in Britain and nine or fewer in the US—would have little effect on the ratios for size of market given in the table. For jute yarn, cured fish, and manufactured ice the ratios would be reduced somewhat. Rostas (*op. cit.*, p. 59), analyzing his data for the thirties, found some interrelationship in that for several industries where the US productivity advantage was greatest the US market was comparatively quite large. Otherwise he found no close relationship. If the data are adjusted by eliminating those industries whose markets tend to be narrowly regional or local rather than national, a moderate relationship between the two variables is observable. But then the task arises of ascertaining the sequence of cause and effect. Are large markets responsible for high productivity and the low real costs usually accompanying it? Or is it that large markets follow upon the prior establishment of high productivity and low costs? The mere coincidence of large markets and high productivity would not answer these questions.

Unless one assumes what it does not appear valid to assume—that productivity levels vary directly and continuously with market size and that the highest productivity levels are associated with the biggest possible size of market—then 50 or 60 million potential consumers should offer as great or almost as great an opportunity for gains from specialization and mass production as 150 or 160 million. Probably all industries are capable of exhausting potential economies within notably smaller confines. Britain's population, moreover, occupies an area but fractionally as large as that of the US. As a result, its industry confronts a market unbroken by the vast transport distances which make for spatial differentiation and hence for smaller effective market size. Thus market size, properly qualified, far from exerting a differential adverse effect on British industry, may constitute a positive advantage to it. E. Rothbarth ("Causes of the Superior Efficiency of U.S.A. Industry as Compared with British Industry," *Economic Journal*, Septem-

ber, 1946, page 384) notes that in 1870 the US market as a whole was probably smaller than the UK market as a whole, while the population of the latter was much more compact and accessible. Yet it appears that US productivity in some industries was even then significantly greater.

Effective market size involves much more, of course, than the sheer number of potential consumers. A fact often referred to is the importance of foreign markets in Britain's demand structure. These, it is said, vary in their nature from one importing country to another, imposing upon the British producer heterogeneous requirements with respect to type and quality, so that economizing long runs of standardized products become impossible. The data confirm that for several of the industries treated in this paper, a fairly large percentage of total output is for export. Of the thirty product groups in the table, British exports as a percentage of production in 1948 exceeded 25 per cent for seven of them. The approximate figures are: bicycles, 69 per cent; razor blades, 46 per cent; fish curing, 41 per cent; wool carpets and rugs, 37 per cent; cotton piece goods, 36 per cent; rubber tires, 32 per cent; sugar, 25 per cent. But even assuming a marked divergence in product requirements between the domestic and the foreign market, the possibility appears for only a few of these that the balance left to the home market is so small as to preclude the use by the bulk of industry of high labor productivity methods. There is no obvious reason—at least to this writer—why the special fabrication techniques that may be suited to export production need set the pace for the economy.

If there be any useful hints in the market hypothesis, they relate not to market size per se nor to export markets but to both the structure of the industry and the structure of the market as these have developed in relation to one another. Where markets for a given product-class are large but highly differentiated, product specialization by firms to a degree compatible with use of highly laborsaving methods may prove impossible. This difficulty is relevant, not only to markets for final products, but equally to intermediate producers' markets. If the demand for semiprocessed raw materials, for components, or for machines is structured and variegated rather than reasonably standardized, the suppliers of these items will experience the same handicaps as will suppliers of finished consumers' goods.

Evidence suggests that in Britain, over a wide range of industries, success in standardization and simplification (the two terms, while sometimes finely distinguished from each other, are here used interchangeably) has been markedly less than in the US. It is uncertain when divergence between the two countries became pronounced. But again differences, as reflected in the degrees to which specialization is carried

out within and among plants, are observable as far back as the middle of the nineteenth century. Especially pertinent are the views expressed by a British group in the early 1850's. It took particular note of the adoption over much of American industry of the "manufacturing principle," according special mention to locks, clocks, small arms, and many branches of the woodworking trade. In the manufacture of locks, for example, it was noted that "all the locks of each description produced are identical, and their parts can be interchanged,"[16] and in woodworking, attention was called to the division of work "into special manufactures where only one kind of article is produced, but in numbers . . . almost in many cases incredible."[17] The British commented on these features of American production because they contrasted with those typical of their own country.

Comments in later years ran in a similar vein. Writing during the first World War, the Board of Trade Engineering Trades Committee called attention to the multiplicity of products produced in each establishment, to the pride many of them took in this state of affairs, and to the confusion and diseconomies that resulted. It compared the situation to that in the US (and Germany) where variety in each plant was limited, and concluded that future progress in the British engineering trades was contingent upon greater standardization and output on a larger scale. (Committee on Industry and Trade, Part IV, *Survey of the Metal Industries* [London: HMSO, 1928], page 146.) The testimony presented during hearings before the Balfour Committee, in the latter part of the twenties, confirmed the need for greater standardization. It indicated also that differentiation was not merely tolerated but in many instances was actively encouraged. (*Ibid.*, page 162, for examples in agricultural machinery and jute.) Suggestions that simplification and standardization policies ought to be pursued often were met with expressions of apprehension that such policies would endanger quality or lose markets through customer dissatisfaction or fix a pattern which time and change would make obsolescent.[18]

Emphasis upon the advantages accruing from standardization and its greater ubiquity in the US than Britain comes also from more recent inquiries. Many of the Anglo-American Productivity Reports stress

[16] *Report of the Committee on the Machinery of the United States of America* (hereafter referred to as the Machinery Report), Sessional Papers, House of Commons, Vol. L, 1854-55, p. 12.

[17] *Ibid.*, p. 64 Observations of the kind cited in the text are found frequently in this report.

[18] *Survey of the Metal Industries, op cit*, pp. 162, 221, 227-228. In connection with bicycles, industry representatives questioned the desirability of a standardized, mass-produced article on grounds that "popular taste would not favor a very cheap bicycle" (pp. 227-228).

this issue. Limitation of variety is strategic because it intertwines with a complex of other factors affecting the productivity level. Its relationship to the use of automatic machinery was mentioned. Such machinery tends to be highly specialized in purpose and hence advantageous only where the identical operation must be repeated many times over. Long runs of uniform products permit this repetition; output in small batches of varied products usually does not. Besides facilitating the use of machinery with its resultant saving in direct labor, product uniformity also saves skills, as machine-tending and the performance of fairly rudimentary tasks replace the craftsmanship of the artisan. It permits more systematic plant layout and workshop organization, so paving the way for continuous processing methods and yet greater division of labor. It eases problems of material handling and warehousing. The interchangeability of parts it entails contributes to reductions in servicing and replacement costs and in the size of inventories. Contrary to popular opinion, product uniformity also may mean better product quality. Constant technical advance has brought improvements in the quality of mass-produced items and worked to diminish quality differences between them and similar items produced by less roundabout methods. Precision methods and quality control—integral features of the newer techniques—have furthered this end. For illustrations, one may look to the auto and textile fields. The distinction between quality goods and standardized goods, always in favor of the former, is no longer so generally acceptable insofar as it relates to the functional characteristics of those goods.

It is not intended here to grant any causal priority to differentiation or lack of it as it relates to other factors affecting productivity. It is not to say, that is, that use in the US of more equipment and less skilled labor results from standardization and simplification. On the contrary, it is plausible that a scarcity of labor, notably skilled labor, in the formative years of this country's industrialization led to mechanization which brought with it, from necessity, a high degree of standardization as well as other features. In the judgment of Wallis (*op. cit.*, pages 2-3), the invention of laborsaving machines, "whose automatic action so completely supplies the place of the more abundant hand labor of older manufacturing countries," was stimulated in the US by the difficulty of securing skilled and disciplined labor. Other hypotheses may well be equally or more plausible. But it seems fairly clear that standardization is closely tied in with other factors bearing on productivity levels and that its presence or absence is associated with the presence or absence of these other factors.

The Effects of Plant Size on Productivity. The question of how plant

size relates to efficiency has been much discussed and investigated. The same question may be raised here, provided we substitute "labor productivity" for "efficiency." The rationale for expecting plant size and productivity to move upwards together is not unlike that for expecting market size and productivity to move upwards together. Opportunities for the application of machines, for specialization, and the division of labor increase as the plant becomes larger, just as they increase, at least up to a point, as the market becomes larger. In the latter case the economies attainable are of both the internal and external kinds while in the former they are mainly internal to the plant.

If the plant size-productivity hypothesis is useful in the present case, then we would hope to discover that US plants are, on the average, larger than British plants and possibly also that the amounts by which they are larger from one industry to another vary with the amounts by which US productivity is greater from one industry to another. The effort to test this hypothesis brings forth a fundamental difficulty: Should plant size be measured by output or by employment? If it is measured by output, then, as with the market-size hypothesis, what cause-and-effect sequence does one impute to a positive finding? Is the productivity of US plants higher because their output is higher, or is their higher output a consequence of the lower costs (or higher incomes) associated with higher productivity? Or is there a mutual interaction between the two variables?[10] Moreover, the output measure neglects the influence of vertical integration which can result in an increase in size (in one sense) without affecting output. If in any industry the plants in one country subcontract much of the work while in another country the plants perform most of the tasks themselves, this difference will not be reflected in an output measure. The 1949 Productivity Report, *Simplification in Industry* (page 8), calls attention to a stronger tendency in the US than Britain toward subcontracting and expresses the view that it aids productivity by making for greater specialization. It also may bias our productivity figures since it reduces the likelihood that a given product classification in the respective censuses will cover the same range of processes.

If employment is used to measure size, these handicaps are bypassed to a certain extent. Differences in both vertical and horizontal integration will generally be reflected in employment differences. The problem of causal sequence will be less serious since, while high productivity,

[10] One might argue that in the US resource conditions, factor-price ratios, and demand conditions favor the construction of large plants (high output plants) and that large plants facilitate high productivity. Or one might take the view that unique managerial talents, cheap resources, or some other circumstance result in high productivity which in turn leads to large plants to meet a large sales demand. There probably is merit in both approaches.

insofar as it implies low costs, will tend always to result in high output, it may conduce to low as well as to high employment. This follows because though high productivity brings high output, thus tending to increase employment, it also brings reduced labor requirements per unit of output, thus tending to reduce employment. Unfortunately, these two offsetting tendencies deprive us of easy criteria for evaluating our statistical findings. Plants are built with the primary object of accommodating a certain output or range of outputs, not a given size labor force. Should we, then, expect employment to be high where productivity is high? Or should we expect it to be low? The answer turns on the elasticity of demand, which is known to vary substantially among industries.

The foregoing qualifications would make difficult interpretation of most data on plant size and productivity, whatever those data showed. If the qualifications are less troublesome for the present study, it is only because the data support no obvious hypothesis. If size of plant is measured by number of workers, then average size of plant is found to be larger in the US in sixteen industries and larger in Britain in eleven industries. In a few instances—biscuits, animal feeds, ice cream, manufactured ice—British plants are considerably larger than those in the US. In a few other instances—cigarettes, cotton piece goods, matches—the picture is reversed, with US plants being two to three times as large. But the data do not sustain any generalization for the whole of industry. The picture does not change when differences between the two countries in plant size are related to differences in productivity. US productivity is usually higher where plant size is smaller. Where US plant size is larger, the degree to which it is larger evidences little relationship to productivity.

Measuring plant size by output, British plants prove to be larger for margarine, beet sugar, and manufactured ice. US plants are considerably larger for cotton piece goods, glass containers, cigarettes, matches, paper bags, radio receiving tubes, tin containers, and wool carpets and rugs. For all the industries, British plants are larger in three cases and US plants in twenty-four cases. While in a few instances—glass containers, tin containers, cigarettes, radio receiving tubes—large differences in plant size coincide with large differences in productivity, no definite judgments on this score seem warranted.

III. *Some Other Factors*

Many factors, in addition to those cited above, affect productivity levels. Only three others—managerial and union attitudes and structures, workshop organization and control, and specialization of labor—will be taken up here. Their effects on productivity are less tangible

and less measurable than the ones already discussed. Perhaps for this reason they rarely are accorded the status of general hypotheses in explanations of Anglo-American productivity differences. Yet their influence appears to be great, particularly so where their interactions with one another or with the resource, equipment, and market factors are considered.

Differences between the two countries in management's approach to production problems and in worker attitudes and practices have been a subject of comment by both early and contemporary observers. The comments differ in detail. But the impressions conveyed by these observers, whether they wrote five, fifty, or a hundred years ago, are in rough agreement on a number of points.[20] Management in the US is less bound by traditional techniques; it responds more readily to new ideas and is prepared to implement them more quickly than its British counterpart. It is more attentive to and seeks more thoroughly to control costs; relatedly, it is more output- and productivity-conscious than is British management. It is comprised to a greater extent of men who have received technical and engineering training and it makes greater use of highly trained specialists of all sorts in filling its advisory and supervisory needs. It is less centralized in its control, is less hesitant to delegate responsibility, and provides at all levels greater opportunity for advancement to those with ability and initiative. Not least, it is more functional and utilitarian in its approach to product design and finish, emphasizing service for the job rather than appearance or quality that is beyond requirements. On the labor side, US workers resist technical changes less than do British workers and accept time-study and job reclassification more readily than do the latter. Less extensive and less rigid craft demarcations also ease the introduction of organizational and technical changes, and a more simplified wage structure contributes to the same end. These same circumstances give management greater latitude generally in administering operations and in adjusting to shifts in demand and supply and so aid accordingly in attainment of higher productivity levels.

Conditions relating to work shop organization and production control seem also to favor the US and to have favored it for a long time. Observers in the last century made reference to the "almost perfect system of manufacture" found in many American trades[21] and to the

[20] These remarks are in the nature of broad impressions conveyed by the literature cited elsewhere in this paper: the Productivity Reports, the Balfour Report, the Mosely Report, the reports of Wallis and Whitworth, and the Machinery Report.

[21] ". . . a considerable number of different trades are carried on in the same way as the cotton manufacture of England, viz., in large factories, with machinery applied to every process, the extreme subdivision of labor and all reduced to an almost perfect system of manufacture." Machinery Report, *op. cit.*, p. 32.

greater attention paid to all details by American manufacturers.[22] The more recent Anglo-American Productivity Reports, in contrasting British and American conditions, refer to good production planning in the US which avoids waste of man and machine hours,[23] to smoothness and continuity in the work flow, to the "excellence of the organization which provides (workers) with . . . the parts and materials they require at the right places at the right times,"[24] to plant layouts that minimize the need for handling and for intraprocess storage,[25] and to a timely and speedy analysis of information on operations that enables production control to operate with maximum effectiveness.[26] Observations of this type occur with such frequency and with reference to so many industries as to suggest applicability to a wide range of manufacturing activity.

Evidence of the greater extent to which the specialization factor has operated in the US is found in two areas. The first concerns the quality of skills among production workers in the two countries. This quality seems always to have differed, with US factories employing a smaller proportion than UK factories of craftsmen who have undergone lengthy apprenticeships. American reliance upon semiskilled and unskilled labor implies specialization of function, just as British reliance upon skilled labor implies its opposite. It is through the breakdown of complex tasks into a lengthy series of rudimentary ones that this country has been able to utilize a comparatively unskilled labor force so effectively. This type of specialization obviously is closely related to the degree of mechanization, since it is mechanization which greatly reduces skill requirements. The second area where labor specialization manifests itself is in administrative, consultative, and supervisory ranks. American industry employs production and design engineers, job-rating men, cost control experts, maintenance personnel and other specialists in larger proportions than British industry.[27] Such specialists are, on the whole, quite skilled. Their employment compensates for the lack of all-round, artisan-type skills available on the shop floor. It also is tied in with the degree of mechanization in that capital-intensive methods are dependent on such skills for their efficient functioning.

An assessment of the relative importance of these factors as against others like resources, equipment, and market structure is no easy task and will not be attempted here. With respect to all of them, however, at

[22] See the article, "American Manufacturing Methods," by a correspondent with the Mosely Commission in *The Times*, Dec. 26, 1902, p. 9-1.

[23] E.g., *Rigid Boxes and Cartons* (1951), p. 5.

[24] E.g., *Diesel Locomotives* (1950), pp. 2-3.

[27] See, e.g., *Diesel Locomotives*, p. 2; *Brushes*, p. 17; *Heavy Chemicals* (1953), p. 9.

least three things seem fairly certain: First, they are factors of consequence and merit a place in any explanatory framework. Second, they register their effects not in isolation but through complex interaction with each other. Third, none is of recent origin, but their roots go back at least to the middle of the nineteenth century. Their different impacts in the US than Britain are the outcome of rather basic differences between the two countries in the processes of economic development.

DISCUSSION

D. H. STEINTHORSON: Data concerning productivity in individual industries are valuable for their own sake, but Mr. Young and Mr. Frankel are interested in these data primarily for the light they throw on the larger problem: What determines the productivity of an economy? In the analysis of this problem, both authors make fruitful use of the comparative and historical approaches. My comments are restricted to Mr. Young's paper.

The productivity of an economy can be inferred from income (or expenditure) data, as well as estimated more directly from production data. Mr. Young's point of departure is a comparison of per capita income in the United States and Canada. Although income per capita reflects other factors in addition to productivity, I think it would be worth while to have estimates, however rough, of per capita income in the regional and industrial components underlying the national totals. These estimates would be useful background to the subsequent discussion and might help meet the objections of those skeptics who doubt whether the two economies are sufficiently similar to make comparisons of average income meaningful.

Having commented on the difference in income per head between the two countries, Young says that after making allowance for labor force participation ratios, the international investment position, and the industrial distribution of employment there remains "a hard core which appears to be of long standing." Allowing for labor force participation and the international investment position is necessary in moving from an income concept to a productivity concept, but I think it is illegitimate in this context to make an allowance for the industrial distribution of employment, since this is partly a product of the process of historical development which has been influenced by tariff policy and other factors the influence of which Young wants to estimate.

In comparing Canadian and American economic development, there are three ways in which we can make experimental reconstructions of history. One way is to ask how the economic development of North America would have worked out north of the Rio Grande had the formation of the Canadian nation in 1867 been followed fairly soon by something approaching economic union with the United States. This would have implied transcontinental railways south of the Great Lakes and free trade between the United States and Canada. In practice, free trade would have meant Canada's adopting the American tariff against other countries. These and other implications would have meant that economic union would have been tantamount to abandoning the idea of building a sovereign nation north of the United States.

The second way of reconstructing history is to ask a more restricted question. We may accept the decision to build a Canadian nation and ask what would have happened if different trade and transportation policies had been adopted. Canada might have had only one railway north of the Lakes (but one would be the minimum) and might have adopted a low tariff in the face of the high American tariff.

The third, and simplest, approach would accept the present situation for what it is and attempt to measure the economic burden borne by Canadians today on account of such avoidable and unavoidable overhead costs of nationhood as the railways across the Shield. This more modest level of abstraction offers less scope for imaginative thinking than do the others but it does have some immediate relevance to public policies affecting income distribution regionally and otherwise.

All three types of question are interesting and legitimate but we must be very careful to distinguish between them. Comments applicable to one type may not be applicable to the others.

Young hopes on some later occasion to say more about Canadian railway policy. For the moment, he reminds us of some familiar historical facts and refers to a tentative comparison of traffic output per worker on Canadian and American railways. To describe the contribution of railways to Canadian productivity one would need to know the productivity ratios for other inputs into railways and the traffic requirements per unit of output in other industries. But neither this information nor the financial data cited by the author would suffice to disentangle the consequences of duplication from the consequences of the geographical distribution of North American resources or the recent competition from other modes of transport. More detailed analysis would be required.

When he turns to tariff policy, Young addresses himself primarily to a question of the second type. He asks whether a low Canadian tariff in the face of a high American tariff would have affected Canadian economic development in such a way as to give Canadians a higher per capita income today than they now have. In suggesting that an appeal to international trade theory should settle the issue, Young is perhaps more optimistic than some others would be. The problem is not to find an optium allocation of resources in given circumstances but the even more tricky one of reconstructing a hypothetical pattern of economic development. There are theoretical models in which a very small exogenous change in the early stages of growth may have very large consequences later on. This proves very little, but it is a warning to us to be careful in performing intellectual experiments on economic history. In referring to a much broader topic than that before us—the evolution of the world economy since the mid-eighteenth century—W. W. Rostow wrote that "modern economic theory offers its students no agreed framework for disciplining such a story of growth and fluctuation." I think that in attempting to discipline the story of Canadian growth and fluctuation Young has tackled a very difficult job.

He will have to face certain questions, particularly those having to do with the applicability to the Canadian situation of the explicit and implicit assumptions belonging to the theory of resource allocation that he cites. Questions concerning the internal and external mobility of resources are crucial to allocation questions. Has protection diminished the flow of resources into the more desirable (unprotected) industries in allowing them to flow into the less desirable (protected) industries? Or has protection merely meant a

larger economy? Has it simply allowed a protected sector of the economy to develop alongside the unprotected sector without diminishing the size of the latter? And if so, to what extent has the greater size of the economy helped to reduce the per capita overhead costs of nationhood and to enlarge the market, incidentally increasing the opportunities to take advantage of economies of scale? And is it really true in the historical circumstances that if the tariff has attracted capital and enterprise, the returns to labor and land must necessarily have been reduced relative to the American? What are the implications of economic fluctuations and unpredictable swings in world demand? Has the presence of protected industries meant that per capita income has been higher than it otherwise would have been when foreign demand for exports has been slack? What have been the dynamic repercussions within the system of economic growth? Have the indirect consequences of protection stimulated economic growth or per capita income? Or the contrary?

Theory creates a very strong presumption that the Canadian tariff is guilty of the charge brought against it, but I should prefer, for the present, neither to acquit nor to convict but to fall back on that Scottish verdict, "Charge not proven." The author deserves our hearty thanks for having embarked on this piece of criminal investigation. He has picked an intriguing subject, and in his further pursuit of it he deserves all our good wishes for resounding success.

W. Duane Evans: I found both of these studies interesting and informative. I shall direct my remarks principally to Mr. Frankel's paper, although the later comments will, I think, have some relevance to the origins and persistence of the Canadian-American productivity differences which Mr. Young finds.

Mr. Frankel begins his paper with a table of rough US/UK productivity differentials for some thirty manufacturing industries (developed from the US *Census of Manufactures* for 1947 and the British *Census of Production* for 1948). He stresses the approximate nature of such comparisons, even when they are based on supposedly comparable physical measures of production, and his points are well taken. Few Americans, for example, with personal experience of British beer are likely to be completely satisfied with any direct physical basis of comparison, and I may add that most Britons feel just the same way about it.

Mr. Frankel says of his group of thirty industries that "there is little reason to suppose that the general impression it conveys of that sector (manufacturing) is seriously misleading." I agree with the statement, but I regard it as far from self-evident. The group certainly gives inadequate representation to the entire metals-machinery-equipment and metals fabrication area of manufacturing, which is represented exclusively by tin containers, pig iron, radio receiving tubes, bicycles, and razor blades. A broader picture is conveyed in the careful and more comprehensive studies of Laszlo Rostas which, however, are based on prewar data. But these, when supplemented by the various available trend studies of Rostas and others, show that the basic

postwar situation remains much the same as before. Mr. Frankel's findings are generally consistent with this very large body of work, and it is the existence of the latter which makes it probable that no serious challenge to the impressions gained from this limited sample of industries will be offered.

The author ranks his industries by the indicated size of the US/UK productivity ratio and remarks that no obvious explanation of the rankings presents itself. I shall suggest (without pressing the point) that, with some exceptions for special reasons, productivity differentials tend to be smaller for items with a relatively static product design and/or technology of production. For example, the product design of a smoked fish remains much the same, and, referring again to Rostas, the US advantage in motor vehicle production is greater than for bicycles, where model changes are somewhat less frequent and drastic.

Mr. Frankel begins his examination of possible causal factors with a discussion of the optimum use of resources in a given environment. I think this might be clarified by contrasting the concepts of efficiency and productivity. Efficiency typically connotes comparison with some more or less explicit standard which represents perfection. Many efficiency concepts are related in a rather static way to productivity. For example, proper skill and application levels in the work force or reduction in rejects and rework in the course of manufacture are efficiency concepts which have relevance to productivity. However, all these notions have one thing in common: once perfection has been achieved, no further improvement is possible. It seems to me that the notion of optimum use of resources in a given environment is a concept of the efficiency type.

Productivity, in contrast, is a ratio without an upper limit. It is closely related in concept with the idea of a changing technology, and its connotations are dynamic. If productivity is doubled, there is no inherent reason why it cannot be doubled again and yet again, and no comparison with perfection or any standard of excellence is implied. One firm, for example, may be highly efficient in the sense that it operates smoothly and without waste of resources in the context of the technology it employs, but at the same time it may be unprogressive, only marginally profitable, and with dim prospects for the future unless changes are made. Another firm may be inefficient in obvious ways, but progressive, productive, and profitable. I think comparable distinctions are important at the national level, and it is not efficiency in any ordinary sense that will be most relevant to international productivity comparisons.

As explanatory hypotheses for the differences in US/UK productivity, Mr. Frankel lists and examines differences in resources, equipment, market size, and plant size. In his final section, he adds differences in managerial and union attitudes and structures, workshop organization and control, and specialization of labor. He suggests that inadequate weight is frequently given in current discussions to these latter factors.

I was a little surprised that no mention was made of differences in labor, management, and consumer attitudes toward competition, and the degree of

competition prevailing. It is difficult to deal with this complex question in any quantitative way, but certainly many economists have felt that it is of importance in understanding productivity differences. Other topics for examination could also be listed, such as the training and educational system for the work force and the general public, distribution and marketing practices, consumer attitudes, the social structure and its effects, the relative importance of financial or production orientation among those who control industry, and many more. However, a number of the topics listed by Mr. Frankel and those which I have added as well seem to be less explanatory hypotheses than subjects for concomitant study. For example, if it is conceded that competition in Great Britain tends to be somewhat more restrained and hence exerts less pressure toward improvements in production techniques—and I believe this to be true—a most relevant question is surely why the role of competition is so different in two countries whose origins and history are so closely linked. I believe the basis for a fairly inclusive generalization exists.

To approach this quite directly, the technical ability of man to alter and reshape his environment, which had changed but gradually over a millennium or two, has jumped in the last two centuries by one to two complete orders of magnitude. The complex modern Western industrial economy, with its vastly different demands on and rewards to the average man, has no counterpart in earlier history. This technical revolution has in turn required far-reaching adjustments and alterations in basic social and economic structures and institutions. In the relatively isolated United States, these profound adjustments were made during a period when labor was scarce, not in relation to capital, which was also scarce, but rather in relation to the abundant opportunities for productive and profitable use which were everywhere evident. Comparable adjustments in Europe and Britain had to be carried through in a period when there was a surplus of labor in relation to visible opportunity. It is suggested that the differences in social and economic institutions and attitudes thus engendered have had a profound, pervasive, and persistent effect on the course of relative technical and economic development.

Some such hypothesis might well be suggested by evidence presented in Mr. Frankel's paper. He avoids one rather common misconception. Some persons, thinking perhaps of the more prominent position of the United States in world affairs following World War I, have been receptive to the facile conclusion that its leadership in productivity is a fairly recent development. It is clear that quite different explanations for the current US advantage will seem reasonable, depending on whether this is a recent happening or one of longer standing. The evidence presented by Mr. Frankel supports this latter conclusion. Indeed, I would not too readily concede even as much as Mr. Frankel, that "the inception of Britain's relative disadvantage belongs somewhere within the past century." One can as reasonably place it earlier. The very fact that productivity differences between the countries have had so long a history is a clear indication that explanations must be sought not in the rapidly changing realm of science and technology per se but rather in the less flexible and longer lived family of institutions and attitudes.

There have been, of course, many contributory factors, some of which have been mentioned. Others might include the linking in the United States of peoples of diverse origins, thus broadening the competition of ideas and avoiding traditionalism; the cultivation of a spirit of enterprise, because those who made the journey across an ocean and to a rough new continent more than a century ago must in the main have possessed it; the spreading of people over a vast land area and the receptiveness to mobility and change this inculcated; and others. Mr. Frankel rightly calls attention to the importance of opportunities on the land and at the frontier in earlier days.

With reference to Mr. Young's paper, I shall here suggest that traditionalism and social and economic institutions patterned to a greater degree around England and the Old World are more common in Canada than in the United States, and hence may have a significant bearing on the existence and continuity of the productivity differences which he finds.

Returning to Mr. Frankel's paper, it is said "the conventionally assumed relationship between land supply, wage rates, and intensive mechanization is not contested here." I think it is quite important to do so, because the conventional approach leads so many simply to the examination of substitution effects. This is an elegant tool for analysis where technology is essentially static, but inappropriate otherwise. Take, for example, a simple situation in the area from which the marginal approach was developed. A new seed variety —and we have new ones nearly every day—may with just the same land, labor, and capital give us substantially greater agricultural production. In other words, productivity has increased in terms of each factor of input, not because of substitution among them, but through the substitution of knowledge for ignorance. Much the same thing may happen when we obtain our textile fibers from chemical equipment and industrial labor in place of the farm land and farm labor used in making cotton. The great discovery of the technical era is that, through knowledge properly applied, we may be able to attain greater realized output in terms of every factor of production. The full significance of this was in no way appreciated in the nineteenth century. I doubt that it is in the twentieth.

I cannot close my remarks without recalling a debt which we can now repay only with remembrance. I refer to the untimely death at Cambridge in October of Dr. Laszlo Rostas, whose contributions to the study of international productivity differences, in my opinion, exceed those of any other man. His initial findings on US/UK differences, published in 1943, were greeted in some quarters with varying amounts of skepticism, amazement, and even indignation. It was his introduction, after valuable earlier work in other fields, to this curious subject where those with the least right to them often seem to hold the strongest opinions. The work of many scholars in subsequent years has served, of course, to validate the conclusions he offered. I am sure that the rather intense public discussions which were aroused by Rostas' work rather startled him, since he was by nature a gentle, quiet, and scholarly man. Nevertheless, it was in the climate created by these discussions that the postwar British productivity improvement program grew. I think it was Rostas'

initial valuable work and his quiet insistence on sticking with the facts which contributed more than anything else to the creation of the Anglo-American Council on Productivity and more recently the British Productivity Council. It branched across the Channel to the productivity work of the Organization for European Economic Co-operation and the more recently created European Productivity Agency, to both of which Rostas contributed personally as well as indirectly. He has richly earned from many of us our lasting gratitude.

REGIONAL ECONOMICS

CRITERIA FOR EVALUATING REGIONAL DEVELOPMENT PROGRAMS

By JOHN V. KRUTILLA[1]
Tennessee Valley Authority

I

A regional development program will suggest different things to different individuals, and to all it is likely to suggest not a single program but a number of related programs focusing on a common objective. To a staff member of a development agency, a regional development program implies literally scores of individual programs ranging from those involving engineering projects to those basically educational in nature carried out co-operatively with educational and other regional institutions. Since these programs are neither comparable nor amenable to uniform methods of analysis, a complete discussion of criteria for their evaluation cannot be attempted in a paper such as this. This paper will discuss the problem only in general terms, therefore, to sketch out at least the nature of the problem and to inquire into some general lines of approach in handling it.

To indicate the scope of the paper and to begin with a common understanding as to terminology, let us start by defining what will be meant by various terms employed.

This paper will skirt the controversy as to what constitutes a region, since opinions among economists vary from a belief that the concept of a region has little value,[2] to the opposite position that there can be demarcated "but one best set of regions."[3] For the purpose of this discussion it will be adequate to define a region simply as an identifiable geographical area, whether a river basin, an administrative unit, or a combination of administrative units, depending on the specific problem at hand. Regions to be considered will be subareas of the United States and thus will represent open economics engaging in interregional trade. The paper will confine itself, also, largely to the problem of relatively underdeveloped regions.

[1] The author is indebted to Pierre Crosson, Henry Erlanger, John Peterson, and Vernon Ruttan, of the TVA, and Otto Eckstein for their comments and suggestions on an earlier draft of the paper.

[2] Rutledge Vining, "The Study of the Spatial Structure of an Economic System." Paper presented at the December, 1951, meetings of the American Economic Association.

[3] Walter Isard, "Some Emerging Concepts and Techniques for Regional Analysis" (*Proceedings* of the Western Exploratory Group of the Social Science Research Council on Regional Economic Analysis, Berkeley, 1952).

Regional development, for our purposes, will be defined as a process resulting in a secular growth of regional output or real income. (This, of course, is less than a comprehensive definition of regional development, as many intangible aspects of development are not susceptible of measurement by a monetary yardstick.) This growth can occur autonomously. It may be influenced, also, by the impact of national economic expansion imparted through the private sector of the economy. A regional development program, therefore, must be distinguished as an influence exogenous to the normal functioning of the private economy. For the purpose of this discussion, a regional development program will be defined as a public undertaking, most likely a governmental undertaking, one of whose primary objectives is to influence the underlying factors affecting regional output.

II

Attempts at evaluating regional development programs in the past have frequently used an aggregate economic indicator, such as total personal income, to compare relative changes for a region in which a development program exists with relative changes for another region. This comparison between two regions over an appropriate time period is assumed to reveal the extent to which development efforts have been economically justified.[4] This procedure is dubious at best for it implies that the development efforts being evaluated, to be effective, must have exercised a dominant influence on regional income—and in the relatively short run. The fact that statistical data which have been compiled in such attempts to evaluate the TVA, for example, have not appreciably influenced the area of agreement regarding the value of TVA programs suggests that this approach falls short of providing evaluative results. An examination of the implicit assumptions underlying this approach will afford some excellent reasons why this may be the case.

First, an evaluation by this method implicitly assumes that the comparison being made is between a region which has a development program and one in which such a program is lacking. But if relative changes in total income are used to measure regional development, the influence of other governmental programs which affect regional income, regardless of the administrative device employed, must be eliminated from both regions to provide the *ceteris paribus* conditions essential for a valid comparison. It is seldom recognized, for example, that the

[4] See, for examples, B. U. Ratchford, "Government Action or Private Enterprise in River Basin Development: An Economist's View," and discussant Joseph Ransmeier's remarks, AEA *Papers and Proceedings*, May, 1951, pp. 304-306, 311-312. Also, "Study of Agricultural and Economic Problems of the Cotton Belt," *Hearings before Special Subcommittee on Cotton of the Committee on Agriculture* (House of Representatives, 80th Congress), p. 687.

activities of the TVA to a considerable extent supplant activities which are carried out by a number of other federal agencies in other regions. The relative magnitude of governmental expenditures for programs other than resource development is likewise almost never taken into account. Federal expenditures for military procurement in California and New York during a five-year period (1950-54), for example, were roughly seven times as large as federal expenditures associated with the TVA over a twenty-one year period. In many other states, although not as large, they were multiples of the twenty-one year total of TVA expenditures. These expenditures, along with grants-in-aid to states, federal construction, and various other direct governmental activities throughout the nation, suggest that the absence of valley authorities does not preclude the possibility that federal expenditures in regions other than the Tennessee Valley account directly for a larger portion of their growth in income.

Second, regional comparisons of income relatives as a method of evaluation implicitly assumes that the activities of development agencies are encompassed within a relatively well-defined geographical area. In reality, since development agencies usually have responsibility for a number of resource problems rather than the economy of a well-defined region, development activities may radiate into adjacent regions observing no common boundary for the entire "package" of resource development programs. For example, the water control program of the TVA is confined to the 125 watershed counties in parts of seven Valley states. The power program relates to a somewhat different area of about 170 counties in these states. TVA's activities in regard to tributary watershed development involve relations with the seven Valley states and its national responsibilities for fertilizer research and development involve co-operative relations with institutions in 35 states. The incidence of benefits stemming from these programs, moreover, is not confined to the areas in which the programs are centered. It is not meaningful, therefore, to take one area influenced by a development program for comparison with another area in which the program's influence has also been felt, in evaluating program results.

Third, such attempts at evaluation involve hidden assumptions that, despite differences in the variety and quality of resources which exist among regions, all regions have a uniform development potential. Stated differently, an assumption is implied that regardless of the differences which may exist among regions in all other determining variables, every region can be expected to develop economically as rapidly as another except for the presence or absence of a development program.

To sum up, then, past attempts to evaluate regional development

programs by comparisons of income relatives have not examined critically what constitutes a regional development program apart from the administrative machinery used to implement it, what constitutes a region for the purpose at hand, and how realistic are other assumptions which are implied to hold.

However, quite apart from these critical observations, there remains another question of importance which seemingly has escaped attention. The degree to which a program can be expected to stimulate regional development depends largely upon the magnitude of the program relative to the total of other factors affecting the region's development. A comprehensive regional development program might conceivably involve responsibilities for monetary and fiscal policy, welfare programs, regulation of transportation rates, interregional trade and migration, and other governmental activities which vary with political philosophies and the contingencies of a particular time and place. Such programs would involve all of the measures with which government can influence the level of income. By contrast, regional development efforts in the United States, such as resource development programs, represent efforts of rather limited scope when viewed in relation to the aggregate of economic activities which engage the productive factors of a region. Given the margin of error in our economic data, is the influence which such limited development programs can be expected to have on regional income capable of being accurately indicated by comparisons of relative changes?

It has been observed by Morgenstern that a probable error of 10 per cent attaches to our estimates of national income. (*On the Accuracy of Economic Observations*, page 84.) There is little reason to believe that estimates of income on the regional level are more accurate. If these estimates are used to provide measures of relative change, a regional development program would have to contribute a third to the income of a region in a given year before its influence would be equal to the range of possible error in an index whose base (prior to program introduction) and given year estimates are subject to a 10 per cent error. To illustrate: The index of estimated income payments from manufacturing for the year 1953 (1929 = 100) was 543 for the 11 southeastern states and 602 for the 201 counties representing the Tennessee Valley and TVA power service area—a difference of 59 percentage points. If we assume that the true income was underestimated for the Tennessee Valley while overestimated for the Southeast in the base year, and overestimated in the given year for the Tennessee Valley while underestimated for the Southeast (all by as little as 10 per cent), the true index would be 664 for the Southeast and but 493

for the Tennessee Valley. If estimating errors of opposite sign but equivalent magnitude for the base and given years are assumed, the true index for the Southeast would be 445 and 735 for the Tennessee Valley. With a range of possible error exceeding 200 percentage points in the index, we cannot feel secure that the indicated difference of 59 percentage points has not been influenced more by errors of estimation than by the development program. Since errors in estimating can produce a wider range of differences in our income relatives than can be realistically anticipated from the influence of limited development programs, one can legitimately question the validity of using comparative data on income (and other) relatives to evaluate development program results.

III

If relative changes in our economic data are not likely to provide a sufficiently accurate basis for evaluating development programs, what alternatives remain? The most fruitful approach, it seems, is one which examines each program activity individually for its impact on the sector of the economy toward which it is directed. One method of this type seeks to provide approximations of real income produced (or losses averted) by such programs which can then be compared quantitatively with costs. This procedure is used to indicate whether the criterion of efficient resourse allocation has been met.

This approach presents several problems. It is desirable to recognize a specific limitation at the outset. Taking the TVA as an example, again, there are programs such as flood control, navigation, and power for which the development agency has exclusive responsibility and from which direct benefits are largely tangible. On the other hand, there are programs, such as tributary watersheds, stream sanitation, forestry, agriculture, and scores of others, which are co-operative ventures involving agencies of state and local government in addition to TVA. These programs involve research, development, and demonstration, in the main, and are fundamentally educational in orientation. Given the state of our research methods and knowledge, developmental results of some of these programs are scarcely less difficult to assay than results of research and public education generally, nor can quantitative valuation be placed on them more easily. With limitations on estimating the benefits of this type of program and shared responsibility for the results, a precise quantitative comparison of benefits and costs from the agency viewpoint does not seem feasible.

This type of program, however, has accounted for only about 10-15 per cent of total expenditures in the case of TVA. The major portion of this relatively small share, moreover, is accounted for by TVA's

national responsibilities for fertilizer research and development and defense chemicals. Costs of the fertilizer and munitions program, while not found in other regions, are largely recovered by sale of munitions to defense establishments and receipts from fertilizers distributed in agricultural programs. Resource development expenditures, apart from the chemical, power, navigation, and flood control programs, therefore, have accounted for only about 3-4 per cent of total program expenditures. The remaining and preponderant portion of expenditures is more readily amenable to quantitative analysis.

Accordingly, an evaluation might proceed by analysis of each program activity which provides opportunity for quantitative evaluation. This will permit judgment as to how efficient an allocation of resources the major portion of program activities represents. In the private sector, of course, the pricing system is assumed to provide a reasonably efficient method of allocation. In the public sector, on the other hand, investment decisions must often be made to provide services which are not available through conventional markets. Public revenues from taxation can be used for these purposes without reference to costs in the capital market, while valuation of the services provided also frequently cannot be obtained directly from the operation of product markets.

This poses a difficult problem of establishing procedures for estimating costs and "returns" to which a good deal of attention has been given and to which a satisfactory solution may emerge. The continuing work of the Subcommittee on Benefits and Costs of the Federal Interagency River Basin Committee[5] is developing a conceptual framework for estimating benefits and costs of river basin projects. Briefly, the method of estimating costs recommended includes imputation of a rate of interest to cover real costs of project capital as well as other costs incurred through conventional factor markets. Valuation of services provided is made by estimating actual or imputed market value of these services, usually measured by the cost of the most economical alternate method of providing similar services. A ratio of benefits to costs is then computed and, assuming that project capital (and other factors) would otherwise be employed at the margin where returns would be just equal to costs, opportunity costs will be met for the total of factors employed in the project if the benefit-cost ratio exceeds unity.

This *ex ante* approach to investment decisions in the public sector can be extended with appropriate modification to evaluation of such

[5] *Proposed Practices for Economic Analysis of River Basin Projects;* see also John M. Clark, Eugene L. Grant, Maurice W. Kelso, *Report of the Panel of Consultants on Secondary or Indirect Benefits of Water-Use Projects,* to Michael W. Straus, Commissioner, Bureau of Reclamation.

programs after they have been in operation. Established operating programs, moreover, provide known construction and operating costs and experience on which to base estimates of benefits. In this connection one consideration bears stressing. Facilities employed in such programs have useful lives which are limited, in the main, only by technological obsolescence. Related development which such programs induce will doubtless require some time to gain momentum. Evaluation of existing programs, therefore, should avoid judgment based on the first year's or an average of early years' results. Cumulative costs over the life of the program should be considered in relation to cumulative benefits expected to accrue over the entire life of the facilities as is done in conventional benefit-cost analyses. Projections based on experience with costs and benefits to date should facilitate estimating realistic cumulative totals. The problem posed by the difference in time distribution of outlays and benefits must be taken into account, of course, and can be handled by use of the interest rate or discount factor.

While this procedure provides criteria for evaluting development programs, it has a national rather than a regional focus; i.e., it is addressed to the problem of allocating resources efficiently within the total economy. Without supplementary analysis to determine the spatial distribution of benefits from program activities, it fails to provide much insight into the effect such programs have had on the development of the region itself. To answer this question, a somewhat different approach may be preferred for analysis and evaluation from a regional viewpoint.

IV

Regional development has been defined as a process resulting in a secular rise in regional output or real income. Increasing regional output and income implies both expansion of the region's productive capacity and growth of effective demand for the region's output. Both conditions are necessary and combined will represent a sufficient condition for regional development. Attention has often been sharply focused on increasing output through stimulating increased participation of underutilized resources and/or increasing the productivity of resources being employed. Perhaps not enough attention has been directed to the process by which effective demand may be increased; namely, through retaining an adequate share of the resulting increased factor receipts in the region to increase the region's effective demand for its own output and ensuring that the increased output include goods and services for which there is a highly elastic demand both from within and outside the region.

The demand aspect in regional development becomes particularly

important when viewed in the light of a rising secular trend in national income. In fact, resource development programs derive their justification largely from the implicit assumption that long-run economic growth will require the factors or services provided by such programs. This assumption must be examined carefully, however, in connection with each program activity. But within the context of an expanding national economy, the degree to which development efforts will make a contribution to underdeveloped regions will depend on how effectively they assist the regions to supply, over time, a greater share of the total economy's expanding demand for goods and services.

Development programs may be evaluated from the regional viewpoint, accordingly, in terms of their aid in increasing the productive capacity of the region and in stimulating effective demand for the region's output.

To promote these dual objectives, resource development programs of the kind undertaken by the federal government should focus attention (within the limitation of their statutory authority) on influencing the supply functions of factors for which demand is highly responsive to secularly rising income nationally. These factors may be referred to as "strategic" factors. They will consist of productive factors for which demand will be relatively elastic both with respect to price and income, and favorably influenced by changing technology and tastes. Development programs which alter favorably the supply functions of strategic resources will improve the region's competitive position in the national market. Cross-elasticity of the derived demand for localized resources will increase the probability that location advantages thus provided will attract external capital to the region. Branch plants of national concerns represent a typical form of such capital movements in a nationally expanding economy. If the strategic factors, furthermore, are required by "growth" industries, i.e., those industries for which product demand is income elastic and influenced positively by the trend in changing consumer preferences, the rate at which capital formation will occur in response to shifts in regional supply functions and the extent to which these and complementary resources will be employed can be expected to increase.

Criteria for evaluating the developmental effects of regional development programs might then be: how effective were the development programs in shifting the supply function of factors on which their efforts were focused and how strategic, as indicated by their demand characteristics, were the factors whose supply functions were thus affected?

As an illustration, we know that multiple-purpose development of the Tennessee River, by altering the production function for the region's

power, produced a substantial shift in the supply schedule. Development of an inland waterway increased the supply of low-cost transport services. The water control program, by regularizing stream flows and permitting settling to occur in the reservoirs, lowered the cost and increased the dependable supply of high-quality processing and cooling water.

We know that these factors, i.e., power, water, and in some cases water transport, are basic inputs in the chemical industry, which incidentally has experienced a half-century of sustained vigorous growth. With respect to product demand, as an example, we know that changing technology, rising income, and changing consumer preferences have altered the derived demand for industrial fibers. There has been a spectacular substitution of synthetic for natural fibers. This in turn has fostered a vigorous demand for factors employed in the production of synthetics. In response to this growing national demand and the procurement advantages in the Tennessee Valley for basic inputs, investment in facilities along the Tennessee River for the production of synthetic fibers has exceeded 50 million dollars during the past several years alone.

Stimulating capital formation is not limited to providing procurement, processing, and distribution advantages directly for new industrial enterprise. Such advantages provided originally may be reinforced by triggered developments. The most spectacular illustration of this in the Tennessee Valley is the developing chemical complex at Calvert City, Kentucky, near the base of Kentucky Dam. The initial development at Calvert City took place in 1948 when Pennsylvania Salt Manufacturing Company erected a hydrofluoric acid plant. In addition to fluorspar, the basic requirements of the firm were relatively low-cost electric energy, large quantities of processing and cooling water, and water transportation for shipment of sulphur and salt. Concurrently, the Pittsburgh Metallurgical Company built facilities for producing ferroalloys to realize savings through joint development of docking and rail facilities. Pennsalt added a chlorine plant which, along with B. F. Goodrich's plans to locate vinyl chloride facilities in the area. prompted construction of a calcium carbide and acetylene plant by Air Reduction. The latter's location decision was influenced by the favorable source of intermediate products supplied jointly by Pennsalt and Goodrich, along with other favorable location characteristics of the area. These three firms now have two plants each at Calvert City which, along with Pittsburgh Metallurgical Company and the recent addition of General Aniline and Film Corporation, represent an investment of approximately 70 million dollars—only slightly short of the total investment in flood

control, navigation, and power facilities of the Kentucky Dam project. This capacity has been built within a period of ten years after completion of the dam. The favorable opportunities for realizing agglomeration economies provided by the developing industrial complex, moreover, suggest a triggered development which in the long run will dwarf the resource development expenditures necessary, although not sufficient, to spark it initially.

Analyses of the industrial demand for power, use of the navigation channel for movement of bulk materials, and use of industrial water supplies in the Tennessee Valley suggest that the water resource development programs have attracted the light metals industries, additive metals using electrometallurgy, synthetic fibers, and other chemical industries. Investment since the beginning of TVA's resource development activities in plant and facilities along the Tennessee River (exclusive of TVA's installations) for which industrial water supplies, water transportation, and/or relatively inexpensive electrial energy are significant location factors, totals approximately 2 billion dollars. Data and conceptual limitations preclude our measuring how much the rate of investment has been increased. We know, however, by computing the location quotients for these industries, that a larger proportion of the rapidly growing new capacity nationally has been built in the Tennessee Valley since the advent of the resource development programs than was being built prior to it.

Although the rate at which capital is formed will affect the rate at which regional income will increase, there may exist a sufficient difference in the ratio of the increment in income to the increment in investment, over time, to merit comment. Investment expenditures of a development program in an underdeveloped region, as well as triggered investment in the early phases of development, will produce something less than the full multiplier effect on that region's income. In the first place, the region will be unable to supply from domestic production a large part of the investment goods required for the program. In the second place, as indicated by family budget studies and the economic structure of underdeveloped regions, the marginal propensity to import from the rest of the economy associated with the second as well as the first round of new expenditures is likely to be very great in relation to the marginal propensity to import from the region by the rest of the national economy. This results from the low income elasticity of demand for a large portion of the region's output (agricultural products, textiles, etc.). The net effect of the regional multiplier will be restricted largely to that produced by expenditures for investment goods and services which can be supplied from regional production. Only a small

additional export multiplier can be anticipated from the national economy's imports from the region resulting from its exports of investment goods to the region.[6] Accordingly, despite the high marginal propensity to consume among low income underdeveloped regions, the region's inelastic supply of investment goods and the low income elasticity of demand for the region's output, in the short run, will limit the multiplier effect of capital formation on the region itself.

If the regional development programs have focused on development of strategic resources, increased factor receipts from the employment of these resources in the region by material-oriented industries will provide, in time, the increment to total income necessary and sufficient to attract market-oriented consumer goods industries for which final demand is income elastic. This process of development reflects a change in the composition as well as level of regional output. If the region thus increases its capacity to supply from home production its demand for income-elastic goods as well as supply a larger part of the expansion in demand originating nationally, *ceteris paribus*, the regional multiplier effect of capital formation both regionally (investment multiplier) and nationally (export multiplier) will tend to increase.[7]

The effects on capital formation and the income multiplier of development programs which improve the region's capacity to supply strategic factors can be contrasted with results to be anticipated from

[6] The regional multiplier in this case will be similar to an investment multiplier involving two countries (cf. Fritz Machlup, *International Trade and the Foreign Trade Multiplier*, pp. 175-176) where the fraction of investment goods and services provided by domestic production is equivalent to "home investment" in the Machlup formulation and the fraction of investment items provided from outside the region is akin to investment in the "second country."

The regional multiplier can be expressed as follows:

$$y = \frac{ai\,(s' + m') + m'a'i}{(s' + m')\,(s + m) - m'm} \quad \text{and} \quad k = \frac{a(s' + m') + m'a'}{(s' + m')\,(s + m) - m'm}$$

Where:

y = change in regional income associated with new investment; i = total amount of new investment; a = fraction of investment goods and services provided by regional capacity; a' = fraction of investment items provided by remainder of the economy, m = marginal propensity to import by the region; m' = marginal propensity to import from the region by remainder of the economy; s = marginal propensity to save in the region; s' = marginal propensity to save of the remainder of the economy; k = the regional multiplier.

[7] The increase in regional income accompanying new capital formation can be obtained from the following expression:

$$y = \frac{ai(s' + m') + m'(a'i + i')}{(s' + m')\,(s + m) - m'm}$$

Where all symbols remain as previously defined while i' represents new investment nationally outside the region. The numerator will be increased by larger values of a and m' in the first term and the increased value of m' which applies to i' as well as the decreased value of a' in the second term. The denominator will be decreased by opposite changes in values of m and m'. The latter follows because of the different order of magnitude in the change in import propensities governed by the relative magnitude of the trading areas.

programs which focus on resources for which demand is relatively inelastic. The agricultural sector is useful as an illustration in this case because final demand for agricultural products generally is characterized by both price and income inelasticity. Growth in demand for agricultural output and hence for total factor input will not be proportional to growth of national income. Although substitution of factors, e.g., fertilizers and capital for land and labor, may result in a derived demand for some factors employed in agriculture to grow more than proportionally with demand for agricultural output, aggregate factor demand in agriculture will be subject to relative decline. Given an absence of production controls and price supports, resource development programs which contribute to increasing the aggregate factor employment in agriculture would tend to affect adversely the terms of trade between agriculture and other sectors of the economy. Because of inelastic demand, income from agriculture may decline by virtue of the increase in output. For a region which is predominantly agricultural and seeks to achieve development through these means, the development effort will produce an extraregional consumers' surplus with regional benefits being eroded away by adverse changes in the terms of interregional trade.

V

In summary, one may conclude that any meaningful evaluation of a regional development program requires intimate knowledge of the many activities which it represents. Furthermore, an approach which attempts to evaluate each program activity individually for its impact on the sector of the economy toward which it is directed is more promising than one which attempts to determine justification for the entire package of development programs by analyses conducted at levels several stages removed from the area of direct program impact. Moreover, it is probable that development programs which are financed nationally have essentially a national rather than a regional focus and that benefits from such programs are not confined within the region in which the program is centered. Regional comparisons of relative change in so-called "economic indicators," therefore, are not appropriate to the problem being posed. Moreover, because of the wide margin of possible error in indexes using such data, they provide a specious measure of the success of regional development programs, even should other conditions required for their use be fulfilled.

Benefit-cost analysis, while approaching the problem at the appropriate level, is designed to provide an investment criterion rather than criteria for evaluating developmental effects on the region in which the program is centered. Perhaps more useful for this latter purpose is an

analysis of the process of development and how regional development programs may influence that process. This requires an examination of the effects such programs have on the parameters of the region's production and consumption functions over time and the trend in the structure of markets. Although precise quantitative criteria may be more difficult to formulate in this case, an approach along these lines is likely to be more relevant, more informative, and more suited for analysis of the dynamic aspects inherent in problems of economic development.

REGIONAL ECONOMIC REACTION PATHS

By F. T. Moore
RAND Corporation

When the economy of a region is subjected to changes in the level of activity of one or more of its sectors, both the real structure of the regional economy and the monetary flow of receipts and expenditures between it and other "economies" affect the character of the response to that change. For a given change in the level of economic activity the effects on income, employment output, etc., will be described as a reaction path for the region. It is the purpose of this paper to suggest certain kinds of changes in economic activity which may prove fruitful to analyze and to attempt to measure quantitatively the effects on specific regional economies of given types of change; that is, to describe certain kinds of these reaction paths. In order to trace reactions to changes in economic activity, it is necessary that the interrelationships among the sectors in the regional economy be specified as to form and be measurable. Although it may be possible to trace through the effects without the aid of a formal model (though on this point I have my doubts), I shall use input-output (or interindustry) models for the states of Utah and of California as the vehicles for measuring regional effects of changes in economic activity; for these kinds of problems such models have virtues which I hope will become apparent as the discussion goes along.

The paper is divided into three parts. First, some discussion of static input-output models, their relevance for regional problems, and the defects which may make the purely static model inadequate is necessary. This section is limited to a very few comments which lead particularly to the model described in the third section of the paper. Second, using the input-output models for Utah and California, changes in income and employment in those states resulting from changes in the "external" demand for individual industries will be examined. The measures developed may be considered as income and employment multipliers. An extension of these techniques also yields estimates of accelerator coefficients for California. Third, the California input-output model will be adapted to the computation methods for linear programing so that a dynamic model of growth over the period 1954-60 may be examined.

I

It is too much to expect that the regions in the United States with which we work will normally exhibit a balanced economic structure.

There is, of course, room for a variety of definitions of the appropriate regional unit, and the economist, geographer, political scientist, and urban specialist can choose the unit most appropriate to his problem. There is merit, I think, in considering the state as a basic unit for regional economic models, since among other reasons, it is sovereign in an interesting area of economic policy making. Unlike the nation-state, however, the police power of the state does not extend to laying restrictions on interstate commerce. Let us consider just a few implications of that prohibition against interference with interstate commerce on the part of states, as it affects regional models and regional analysis.

In constructing a regional input-output model such as the ones for Utah and California which are used later in this paper, the analyst has the choice of letting the cells show the total demands of the industries in the state without distinguishing those demands satisfied by industrial capacity in the state from those satisfied by "imports." Alternatively, the gross flows table can be constructed so as to show the intrastate flows alone, relegating imports (and exports) to the exogenous final demand sectors. The Utah and California models follow the second method with the result that the intrastate flows are well articulated, but a side calculation of serious proportions is necessary in order to account properly for imports. All this is old hat to the seasoned input-output analyst, but consider how it complicates the analysis of regional growth. For a given regional input-output model, assume that the outputs from all industries necessary to support the delivery of a given level of final demand (for example, regional consumption and investment demands, and exports) have been computed. A comparison between the required level of output and regional capacity can then be made for each industry individually. If for one or more industries required output is greater than capacity, a choice is implied between building new capacity in the region or raising imports. Short-run prospects of drawing down existing inventories or rationing of demand through price increases are ruled out for the moment.

Whether the region becomes permanently a deficit area by increasing imports or makes a readjustment by building new capacity depends on the cost comparisons, not only in the deficit industries, but in all industries in the region. If some industries have exportable surpluses while others have deficits, comparative cost studies will determine the most desirable course of action. The deficits may accumulate; or the region's comparative cost advantages may point to a further development of the industries which already are net exporters. If a choice must be made between two deficit industries, the cost studies will show the efficient relative rate of growth of the two in the region. In any case, a formal input-output model does not automatically supply the answer

or the criteria by which the choice is to be made. All it can show is the "trade off" in real cost between development in one industry and the alternatives of development in other industries which are thereby foregone. The direct cost of adding a unit of capacity to a given industry is measured by the set of capital coefficients (i.e., the real quantities demanded in constant dollars per unit of capacity) appropriate to that industry. An increase of X units in capacity thus requires X times each capital coefficient from other industries in the state or from imports.

The problem may be framed in another way to ask whether a given bill of goods is feasible in a static model which allows capital building to take place but which makes no explicit allowance for time lags. Assume as before that for the given bill of goods the output required to satisfy it has been determined by multiplying the vector of final demand by the inverse matrix, thus getting both the direct and indirect requirements for output. If the generated output is greater than existing capacity for one or more industries, new capacity building must take place. This in turn places additional requirements on the other industries in the region, and one or more of these suppliers may in turn require an expansion of facilities. Such a model thus gives rise to two sets of equations of the following form:

$$(1)\ X_i = \Sigma_j a_{ij} X_j + \Sigma_j b_{ij} m_j + f_i$$
$$(2)\ C_i = X_i - m_i + u_i$$

where X_i = current output; C_i = initial capacity; f_i = final demand; u_i = unused capacity—all for industry i and where $[a_{ij}]$ and $[b_{ij}]$ are flow and capital coefficients respectively; m is the vector of additions to capacity built during the period under analysis.

The first set of equations shows the disposition of current output among the alternative uses of sales on current and capital account and to final users. The second set of equations simply shows the allocation of capacity to uses including the possibility of its being unused. These equations thus are perfectly straightforward applications of social accounts principles. They may be compared with the equations in the third section of this paper.

Since choices between use of resources on current or on capital account may be made, this model could be calculated by linear programing methods; but since it is a purely static model, there are no lags in building and using new capacity so that the solution, if there is one, must satisfy the final demand subject to the restriction that capacity must be at least equal to requirements for output from this industry on current account and capital account. There may be no solution, since each capacity expansion in one industry may generate new capacity requirements in other industries. The model then "explodes."

Thus, such a static model, even if expertly used, may be inadequate to handle relatively simple dynamic situations. The model suggested in the third section of this paper is an attempt to move to a more meaningful formulation for handling time lags on production and capacity building and for showing the time paths of output in growth models.

II

The changes in economic activity which affect the regional economy may arise either internally or externally; that is, as a result of growth within the region, a shift in the composition of demand in the region or as a result of changes in the level of economic activity in the nation which in turn affect the regional economy. Both kinds of changes are important; a growth in population in the region will raise consumer demand for products and services and will perhaps shift the composition of demand among industries, or it may simply raise the level of demand without changing its composition. The development of a new resource will inject new investment flows into the region; thus engaging the multiplier process with its direct and induced effects on income and employment. Or a change in the federal budget—let us say the expenditures on defense—will most certainly have an effect on the economy of California which has a big aircraft industry, shipbuilding, and many military installations. In fact, almost any change in the gross national product will change the demand for the products of some industries in the region and will, within a short time, have an effect on income and employment and the general level of regional economic activity.

In an open input-output model, all of the above types of changes are covered in one or more of the sectors of final demand. It is common to distinguish in final demand the sectors: household (consumption), producers' durables (part of investment), construction, federal, state, and local government, and exports. All of these are exogenous or external to the main structure of the model. The levels of these sectors must be specified independently. Then these final demands and the coefficients of the model determine uniquely the levels of output required. As the final demands change due to any of the factors mentioned above, the output levels (and hence income and employment) will also change. Thus for convenience in measurement, we may lump all such changes in final demand, without specifying the type of change, and go on to compute the multiplier effects on regional income and employment of any type of change in "external" demand.

The precise character of the change in external demand—whether the result of new investment arising autonomously, new consumption resulting from population growth, etc.—need not be defined at the moment, since the multiplier effects of changes in levels of activity can be carried

out in terms of a unit (one or one million dollars), and the direct and indirect effects of the changes can be evaluated.

When a change in final demand occurs in one or more industries, the immediate impact is likely to be on finished inventories of the product but as soon as production plans can be readjusted, the change will be translated into changes in output. Let us call this direct output change (equals change in final demand) for industry k, Δf_k and let us assume it has the unit value of $1.00. Now the direct effects on income can be obtained by multiplying Δf_k by the household coefficient for industry k, that is, a_{hk}. This coefficient, it will be recalled, shows the payments made to households (as a sector) in the form of wages, salaries, etc., per dollar of output.

The direct change in output in k will, however, cause the industries supplying k to readjust their own production plans, and these adjustments will set off third- and fourth-order reactions. A cut in output by industry k will thus have both direct and indirect effects on output, each industry both affecting and being affected by the "rounds" of these changes. The direct-plus-indirect effects on the output of all other industries of a change in output by industry k are shown by the *k-th* column of coefficients in the inverse matrix. Define $(I\text{-}A)^{-1} \equiv [d_{ij}]$. Then d_{2k} shows the direct-plus-indirect effects on industry 2 of a $1.00 change in the final demand for industry k. Then it follows that the direct plus indirect effects on income of a $1.00 change in final demand for industry k are given by: . .

$$a_{h1}\, d_{1k} + a_{h2}\, d_{2k} + \ldots + a_{hn}\, d_{nk} = \Sigma_j\, a_{hj}\, d_{jk}$$

and the direct income effects (for the $1.00 change) are given simply by the household coefficient, a_{hk}. We now define the "simple" income multiplier as the ratio of the direct-plus-indirect income effects to the direct alone.

$$M_k = \frac{\Sigma\, a_{hj}\, d_{jk}}{a_{hk}}$$

where M_k is the simple income multiplier for k. Such multipliers have been computed for each industry in the regional input-output models of Utah and California; they are shown in Table 1 together with multipliers computed from a US model for comparison.

Each column of multipliers taken separately can be interpreted without confusion, but comparisons among the multipliers for a given industry in the three models should only be made with the greatest of care. As can be seen from Table 1, the number of industries is not the same for the three models; thus the aggregations which have been performed result in industry classifications which are most difficult to compare. The California model was aggregated from a basic 56 order

model and Utah a basic 26 order model. To what extent the multipliers are sensitive to the changes in the classification system resulting from different kinds of aggregation is not known with any certainty, but the sensitivities are perhaps substantial. In California, petroleum is by far the largest part of the industry, "petroleum and fuels," whereas in Utah coal is larger. Contrasts of the same kind could be made for other in-

† In the Utah model these industries were lumped under "Other manufacturing" with a value of 1.44

‡ In the Utah model this was split into two industries with multiplier values as follows: iron and steel, 2.52; nonferrous metals 8.11.

§ Included with processed foods, textiles and apparel.

** Split and included both in primary metals and petroleum and fuels

†† Included with petroleum and fuels.

SOURCES: The California figures are from an unpublished input-output study by the writer and Dr. James Petersen, of the RAND Corporation; the Utah figures are from a paper, "Regional Analysis: An Interindustry Model of Utah," by the same authors and soon to be published in the *Review of Economics and Statistics;* the US figures are from a model basically representing an aggregation of the 1947 national interindustry model. All three models are in 1947 dollars.

dustries, so that the economic meaning of comparisons of the multipliers may be greatly vitiated.

There is one explanation for the differences between the state and US multipliers which is at least consistent with the observed numerical results. For every industry in Table 1, the multipliers applicable to the national model are larger than for the corresponding figures for Utah and California, and in virtually every case the difference appears to be substantial. It is reasonable to explain the lower values for the states as due to the leakages which occur in the purchase of goods and materials as successive industries readjust their output. There are a num-

ber of products which Utah and California do not produce or do not produce in sufficient quantity to satisfy the demands of other industries in the state as the general level of economic activity increases. Even when a decrease in activity is experienced it is not certain that imports will suffer the most since the state industries may not possess cost advantages. Imports and exports bulk larger in the states' economies than in the nation's. If output is to be expanded, a part of the expenditures will go for imports, thus leaking out of the receipts and expenditure stream of the state. On the other hand, of course, exports inject new flows of receipts into the state. Whether on balance the leakages occasioned by the imports are larger than the stimulus supplied by exports will depend on the specific circumstances. It is probable that the effects will be different for a general increase in output from what they are for a decrease. In both the Utah and California models, imports seem to be of such importance in the large that the income multipliers are smaller than for the corresponding industries in the US.[1]

A look at the income multipliers for a state such as California reveals some interesting things. The larger the multiplier, the greater is the relative impact of that industry on the economy of the state, and conversely the closer the multiplier value is to 1, the smaller is the relative effect. In California, the processed food industry with a multiplier value of 3.32 and the primary metals and foundries industry with 2.21 have the greatest relative impact. In Utah, the nonferrous metals industry with a multiplier value of 8.11 is by far the most important to the economic health of the state. These multiplier values have a simple interpretation. In California, if output in the processed foods industry drops in such a way that direct income payments are cut by 1 million dollars, the effects of the cut in production would result in California income dropping by 3.32 millions in total. The indirect effects account for 2.32 million dollars of the total.

We must beware, however, of confusing the relative impacts, which these multipliers measure, with the absolute impacts on income of any given industry. In some industries wage and other income payments are a larger percentage of total cost than in others; so that output need change smaller amount to account for a $1.00 change in direct income payments. Furthermore, we have not said anything about the sensitivity of output to change (i.e., the frequency of change) nor the expected

[1] In his study of the Pacific Northwest, Paul Simpson derived a formula for a static regional multiplier which leads to smaller values than for the nation. The formula is $m = \frac{1 + q_c}{q_s + q_c}$ where m = regional multiplier; q_s = marginal propensity to save; q_c = ratio of imports of consumption goods to home produced consumption goods. Cf. *Regional Aspects of Business Cycles and Special Studies of the Pacific Northwest*, a study prepared for the Bonneville Administration, June, 1953.

amplitudes of change in unstable conditions. Both the frequency and the amplitude of change in output in the cycle are important measurements to consider when assessing the absolute impacts of a change in production in a given industry on the state's income.

It will be noticed that Table 1 is labeled "simple" income multipliers and for good reason. There the initial changes in final demand were translated into the direct-plus-indirect effects on income via changes in industry output. No other relationships were admitted to the calculation. But as incomes change, consumer expenditures on goods and services will ordinarily change also. Since consumer expenditures are one sector of final demand, the changes in income described above will lead to changes in final demand (i.e., consumer expenditures), and that in turn will set off a second round of readjustment of output, of income, and back again to final demand for the third time and so on to fourth, fifth, and later rounds. This circular flow of adjustments in final demand, output, income and back again can be carried through directly via an iterative procedure in the manner just described or the consumption-income relationship can be incorporated in the structure of the input-output model by augmenting the original inverse matrix by the household row and column. If this is done, the coefficients in the household row of the augmented inverse show the total effects on income (that is, the direct, indirect, and induced effects) of a $1.00 change in final demand for each of the industries in the model. What has been added by this procedure are the effects on output and income induced via the consumption-income relationship. This relationship may be linear and homogeneous or may be of the more usual form, linear and nonhomogeneous: that is, of the general linear form $a + bx$; b, as the marginal propensity to consume, can be used in the household column of coefficients with which to augment the original inverse and the values of a remain in final demand as a stipulated amount of consumption expenditure. Income multipliers of this sort have been computed for Utah alone.[2] As might be expected, the effect of the introduction of the consumption-income relationship is to raise all the multipliers.

We might now relax the conditions of the problem to admit one more type of relationship: the effects upon investment induced by the changes in income and consumption. This calls for a calculation of accelerator coefficients for the region, but it also does more than that. We should have to predict, for given time profiles of production associated with given bills of goods, the division between the additions to demand satis-

[2] Cf. forthcoming articles on "Regional Analysis: An Interindustry Model of Utah," *op. cit.* In that paper employment multipliers are derived as a supplement to the income multipliers. They are of interest in themselves, but the technical problems of their derivation are similar to those for income multipliers so that it was felt that they could be omitted from discussion here.

fied from imports from those satisfied by new capacity building in the region. Now we have come back full circle to one of the problems mentioned briefly in the first section of the paper. To get first approximations to accelerator coefficients is easy. The numerator of the formula for the calculation of the income multipliers can be used, but with the capital-output ratios or coefficients substituted for the household coefficients. For industry k the accelerator coefficient would be estimated by

$$R_k = b_1 d_{1k} + b_2 d_{2k} + \ldots + b_n d_{nk} = \Sigma_j b_j d_{jk}$$

where R_k = accelerator coefficient (per $1.00 change in final demand for industry k); the b's are the capital-output ratios and the d_{ij}, as before, are the coefficients in the inverse matrix.

These coefficients can only be interpreted as measuring the amount of capital directly and indirectly utilized per $1.00 of final demand for the given industry.[3] It is possible to argue that these are only average accelerators and that the marginal figures would be quite different. But over and above the difficulty of agreeing on some numerical values, there is the greater difficulty of meshing the various economic events: the initiating change in some sector of final demand; the changes in output, income, and consumption resulting therefrom; the changes in investment induced as a result and the multiplying effects on income flowing from it: and so on and on. An extremely meticulous analysis of each of these phenomena might make some progress laboriously toward a solution, but since time lags and the necessity of choosing the activities to be performed are met at each point, a model structure to handle these problems and to program them efficiently seems essential.

III

The input-output models described above are static, although by a careful dating of each event an analysis of the whole system may be made which does resemble the dynamic situation. Tracing through the effects of an initial given change in final demand, as was described in the derivation of the multipliers, is a step in the direction of dynamic analysis; but it may be possible to include most of these economic events in a model which will determine whether given schedules of final demand over time are feasible and what the efficient programs are. The model structure to be developed will be used to predict growth in the

[3] Accelerator coefficients were computed for the California model. On the assumption that they may have some curiosity value, the following numbers are presented: Agriculture 2.48; mining .68; petroleum 2.47; processed foods 1.63; textiles .72; lumber, etc. 1.11; other manufacturing 1.22; primary metals 1.85; fabricated metals, 1.31; nonelectrical machinery 1.59; electrical machinery 1.09; transportation equipment 1.34; utilities 2.62; trade 1.25; services 1.20.

California economy for 1954-60, although the model may be used for analysis of many problems other than growth.[4]

Let us start with some simple social accounts and ask how current output is divided among these accounts. We shall denote the output of industry i in the time period t, X_{it}, $i = 1,2, \ldots n$; $t = 1,2, \ldots T$. A part of this output will go to final demand which consists of the output taken by private consumers, by federal, state, and local governments, by exports, and by autonomous investment. As we shall see, investment is divided between that which is determined by exogeneous factors (autonomous investment) and that which the model plans itself in order to meet a desired build-up in final demand (i.e., induced investment). The drain on output arising from the former is included in final demand, and, using the same symbols for i and t as before, final demand is denoted f_{it}.

Output of industry i is also required by other industries in the model, first, in order to produce their own current output and, second, in order to build new capacity (i.e., induced investment planned in the model). Demands on industry i on current account by industries $j = 1,2 \ldots n$ are given (per unit of output) by the standard flow coefficients, a_{ij}, and those on capital account by the capital coefficients, b_{ij}. If all industries are considered together, these two requirements are denoted by the matrices, $A = [a_{ij}]$; $B = [b_{ij}]$. Induced investment, to be determined in the model, is denoted m_{it}. Our last account represents that part of output which is not used up in the current period but which is stored for use later and is denoted, s_{it}.

Now let us account for the capacity, c_{it}, which exists in a given industry at any time t_k. It is simply the initial capacity in the industry plus any capacity built in the periods $t = 1,2 \ldots k\text{-}1$ (we shall assume that autonomous investment is zero in this model); this capacity is distributed between the production of current output and that part which lies idle or unused, u_{it}. Thus at t_k initial capacity is equal to output in t_k plus unused capacity in t_k minus the additions to capacity up through t_{k-1}.

The accounts for all industries in the model can now be summarized in two sets of equations. The first subscripts denoting the specific industry will be suppressed and x_t, f_t, m_t, s_t, c_t, and u_t will designate column vectors; together with the flow and capital coefficient matrices

[4] I am indebted to several people for their help in developing this model: to James Petersen, RAND Corporation, with whom I worked, and am continuing to work, on the California flow input-output model; to Harvey Wagner, formerly of the RAND Corporation, with whom I discussed at length models of this type and who developed a short-cut which halved the number of equations in the computation (his technique has great promise for other linear programing models); to William Orchard-Hays, RAND Corporation, who carried out the calculation on the IBM 701.

A and B they constitute the materials for setting down the accounts in the form of difference equations.

$$(1)\quad X_t = f_t + AX_t + Bm_t + S_t - S_{t-1}$$

$$(2)\quad C_t = X_t + u_t - \sum_{t=1}^{t-1} m_t$$

The first set of equations simply accounts for current output, allowing for the storage of output and for the use of output produced in the preceding period. The last two terms thus show the net change in inventories of finished products. The second set of equations relates initial capacity to its usage in current production, that which is unused, and the programed new capacity.

By using the equations above but casting them into a convenient

linear programing formulation and writing out the form for a series of time periods, the model appears as in Figure 1. Some rearrangement of the terms in the first equation has also been made. The column heading (e.g., x_1, m_1, etc.) denote the activities occurring over time; each of the headings x_1, m_1, x_2, etc., denotes a column vector which is to be premultiplied by the matrices appearing in its own column. If that is done, the equations above are reconstructed. The equality sign appears just after the column vectors of final demands and initial capacities.

From Figure 1 certain potential properties of the model become evident. As it is written there are no production lag times for current output. Output is produced and is available within a single period. The use of $(I\text{-}A)$ in each period shows this to be the case, and for this particular model for which one year is the unit of time it is quite reasonable

to suppose that no lag times are greater than one year. But assume that each period were fifteen days long. Then it would be essential to specify the lag (or lead) times on each input coefficient as well as to date the maturing of output. This can be done easily (if the information is available) by placing the a_{ij}'s with the appropriate leads in the various time periods. To take one example, suppose that of input a_{12}, 40 per cent is required in the first period, 30 per cent in the second, and 30 per cent in the third, and that if that is done, one unit of X_2 matures in period four. Then one column vector under X would contain $.4a_{12}$ in $t = 1$, $.3a_{12}$ in $t = 2$ and so on, with one unit of X_2 in $t = 4$. This splitting of the time period would also affect the storage activities, s_i, since stock piling could occur and be available only after the output had matured.

In this model there is a one-period lag on the building of new capacity, however. The capacity which is ready to produce in t_k must be built (i.e., the inputs must be available) in t_{k-1}. Again it would be possible to have varying lead times on capital and on the availability of capacity. If partial production can be obtained before the new capacity is completely finished, the identity matrices I under m can be modified to show the availability of this partial production. They can also be modified to show the depreciation of capital. In this model capacity built in t_1 is available without depreciation in all subsequent periods, but if depreciation of capital of, say, 10 per cent per year is to be shown the identity matrices I under m would have values of $.9I$ in the third time period and successively lower values thereafter; thus reflecting the depreciation of capacity.

As a final point it should be noted that the flow and capital coefficients, A and B, can be changed in any period so as better to represent costs or production methods through time. The production functions can be modified to show shifts among suppliers, changes in techniques, or increases in efficiency. The capital coefficients can be adjusted to show the marginal costs of adding to capacity in a given industry. However, these changes must be foreseen in setting up the original model since they affect the whole structure.

The California model has sixteen industries, two sets of equations (one referring to current output and inputs; one to capacity utilization), and there are four kinds of activities; hence the original form of the model contained $2nt = 192$ rows, and $4nt = 384$ activities. A computation short cut reduced this to 96 rows and 288 activities, which is the form in which the model is computed. The model is to test the feasibility of certain rates of growth in final demand over the six years. Final demand in this case means consumer demand and federal, state, and local government purchases of final products. Autonomous invest-

ment was assumed to be zero, and imports and exports were specifically excluded for reasons discussed later.

Estimates of final demand in 1953 for each of the sixteen industries were made by starting with the 1947 final demand from the California gross flows study and by projecting forward to 1953, taking into account population growth, shifts in the relative positions of industry, etc. Capacities for the industries in 1953 were also estimated and the final demands and capacities for the model are shown in Table 2. In a short paper such as this, it is impossible to show the matrices of flow and

TABLE 2

1953 FINAL DEMAND AND INDUSTRY CAPACITIES FOR THE CALIFORNIA GROWTH MODEL

* Millions of 1947 dollars.

capital coefficients which were used. Suffice it to say that the flow coefficients were derived from a gross flows table of sixteen industries which itself was a condensation of a fifty-six order table, and the capital coefficients were estimated using the series of input-output studies on capital coefficients as guides. All figures used in the model are in 1947 dollars.

The feasibility of various rates of growth of final demand over the six-year period are being considered in the computation. Seven separate cases in ascending size have been specified, consisting of uniform or mixed percentage increases over 1953. These seven cases are: (*a*) 2 per cent increase in final demand per year for all industries; (*b*) 2 per cent for industries numbered 1, 2, 3, 4, 6, 8, 9, 12 and 5 per cent for industries numbered 5, 7, 10, 11, 13, 14, 15, 16; (*c*) 5 per cent for all industries; (*d*) 2 per cent and 10 per cent for the same respective groups as in *b*; (*e*) 5 per cent and 10 per cent; (*f*) 10 per cent;

(*g*) 15 per cent. The differential rates of growth for the two groups of industries require at least a passing explanation. A summary appraisal of the industries, gained in part during the course of the projecting final demands from 1947 to 1953, seemed to indicate rapid growth in demand for some industries such as trade, services, and construction, since, with the growth of population in California, these industries which minister most directly to consumers may be expected to experience extensions of their markets at least equal to the rate of population growth and perhaps much more. Other industries which depend on export markets or which are tied to a natural resource might be expected to grow more slowly; that is, the percentage of final demand satisfied by the industry in the state as compared to the percentage from imports might be expected to decline. In this rather labored way, a very rough justice had to be done to a number of factors. The possible combinations of rates of growth between 0 per cent and, say, 25 per cent for sixteen industries is infinite, and some reasonable combinations of growth rates had to be selected. A more painstaking analysis might demonstrate that the rates selected are nonsense, though I believe on first blush that they are at least within the acceptable range.

The model was first asked to produce in all periods a feasible program for 1953, the initial year. By definition such a program exists if the coefficients, final demands, and capacities are accurate. Then the rates of growth corresponding to the first case described above were introduced in the final demand positions of the equations and tested for feasibility. The successively higher rates of growth will be tested until infeasibility occurs for some rate. Then the optimum program for the highest feasible rate will indicate the growth pattern for the state. At the time of writing, only the 2 per cent case had been computed. The remaining cases for the higher rates of growth are still to be tested. For each industry in the model an increase of final demand of 2 per cent per year has been found feasible, and the program of outputs has been determined. The ninety-six activities to be performed are not worth while setting down in detailed tabular form since the 2 per cent case is just an intermediate stage in determining the maximum rate of growth of which the California economy is capable over the period 1954-60, but some general summary of the character of the results may be instructive:

1. Given the final demand and capacities of Table 2, the 2 per cent case required new capacity building in only three industries: utilities, trade, and services. All other industries had sufficient capacity.

2. Because of the existence of excess capacity, particularly in the first two years of this period, stock-piling activities were carried on quite

extensively in many industries. The levels of stock piling attained in some industries were surprisingly high, indicating that for that low a rate of growth there is a great deal of slack, probably too much to represent any real situation.

3. Since new capacity building was at a minimum, industries such as fabricated metals and construction, which feed capacity expansions, had a great deal of idle capacity.

4. Output levels over time have different patterns as among the industries in the model: some output levels rise steadily (e.g., agriculture); some remain constant (e.g., primary metals); some fluctuate up and down (e.g., lumber, furniture, paper).

It seems evident that higher rates of growth than 2 per cent will prove feasible, since excess capacity exists in most industries. Subsequent calculations will determine how high a rate may be obtained. However, the low level of output of some industries such as transportation equipment is significant by itself because of what it implies about our definition of final demand. Only consumers' demand and the demands of government are included, whereas in the input-output study of California a large portion of the output of this industry was represented by "export" demand. Had we included exports in our final demand vector, this idle capacity probably would not have occurred and the programs of output would have been quite different. Our higher rates of growth will reduce this idle capacity, but the situation is really one of having a set of requirements which does not "drive" the model in the way that seems most realistic. We shall have to redefine our final demand in some way to incorporate the important category of exports in our regional growth models.

There is another important variable whose exclusion biases or limits the applicability of the results, and that is imports. The California model really asks what rate of growth is feasible with the resources (capital) immediately at its command; but the import of certain kinds of products such as steel probably will always be the largest part of total demand in the state. The cost comparisons between domestic products and imports, which are so important for the individual industry decisions to invest in new plant and equipment, are missing from the model. If there is a need for new steel capacity and the resources are available, the model will program such building. Now imports might have been included in the model in several ways; by adding them without a constraint on their amount, any rate of growth is feasible. But ask yourself: what sets the limit to imports into a state? It is most perplexing to try to set down the factors limiting imports. Is it limited by public and private savings plus the ability to create new debts, and if so, what

limits the latter? It is obvious that we need some careful analyses of regional money flows, of regional demand patterns, of comparative costs of producing different products, etc.

Imports might have been included as an additional activity in the model and then either an absolute limit put on the total, thus allowing imports to occur freely up to that point, or by the choice of an appropriate price for imports the model might have been computed so as to minimize the cost of imports. Once the model is computed, the shadow prices which automatically emerge can be used to determine whether any new activitiy will be profitable or not. Explorations along these lines will undoubtedly prove fruitful for more sophisticated and realistic regional analyses.

A second factor about whose impact we know very little is the number of periods over which the model is run and the period(s) at which peak demand occurs. If the model had been run over, say, twenty periods with different time profiles of final demand and with peaks for some industries occurring in staccato during the planning period, the programing of capital building and current output might well exhibit great differences from the program for the planning horizon of five periods, and if, at the same time, each period were set equal to a quarter rather than a year we might well believe that each group of four periods (a year) would show marked differences from this particular model. It will be necessary to run a number of calculations on one model, varying some of the parameters each time, in order to determine the effects of these and other factors. Plans have been made by the author and others to run a small (perhaps ten-industry) national model a number of times, varying some of the parameters each time.

Some of the problems which appear to be quite difficult for a regional model would be less so for a national model, and I believe that the model is much better suited to analyze growth or fluctuations in the national economy. I suspect that the limitations imposed by labor availability, imports, etc., can be handled in more realistic fashion for the nation than they can for a state. Part of this stems from the better data and more thorough background analyses made of data on the nation, and part is attributable to the fact that whereas the commerce between states is subject to very few restraints, the commerce between nations is frequently such that it is not too hard to guess how the choices are going to be made.

DISCUSSION

PHILIP NEIFF: These two papers provide a number of exceedingly interesting contrasts, due principally to a basic difference between the approaches adopted by the authors. Mr. Krutilla sees the shortcomings of data as so significant as to preclude the quantitative evaluation of any but direct effects of development programs, preferring, apparently, informal appraisals of all secondary or "triggered" development. Mr. Moore, while undoubtedly well aware of the shortcomings of his basic data, obviously prefers to use it to the limit, perhaps hoping the statistical requirements of his model will affect (possibly "fix") the operations of agencies responsible for the collection and publication of economic statistics. My own inclination, in spite of serious doubts that a unique value attaches to the input-output approach (a virtue that I fear some of Mr. Moore's "seasoned" input-output analysts claim), is to side with Mr. Moore. A flight from quantitative measures to subjective appraisal is a temptation to any social scientist. The identification of cause, the appropriate weighting of multiple causes, and the evaluation of multiple effects is certainly discouraging, difficult, and sometimes impossible given the analytical tools and the data now available. But this does not justify recourse to methods or approaches that at best can provide tentative and partial answers to important questions.

Mr. Krutilla rejects the evaluation of regional development programs by comparisons of growth rates of aggregate income series among regions on the following grounds:

1. Other governmental programs, e.g., military procurement, affect regions differentially.

2. It is impossible to establish one set of boundaries within which are confined all effects of such programs.

3. Such an evaluation assumes that all regions have equal development potential.

4. Development programs are relatively unimportant compared with all other influences on regional income. Since it is impossible to abstract from these other influences, income comparisons fail to measure the contribution of such programs.

As I see it, these four limitations add up to the fact that results (income changes) cannot easily be traced to their many causes: resource complement, export demand, military procurement, government investment, etc.

Mr. Krutilla offers as a substitute a method for evaluating the comparison of costs and benefits of those programs of a development agency such as flood control, navigation, and power for which the development agency has exclusive responsibility "and from which direct benefits are largely tangible." Somewhat later in the paper he implies that costs and benefits are readily measurable, too. Cost estimating apparently worries Mr. Krutilla not at all. In fact the market value of the services rendered by the agency is usually measured by the cost of the "most economical alternative method of

providing similar services." The development program's success is then apparently indicated by the extent to which the benefit-cost ratio exceeds unity. My doubts that costs and benefits are tangible and measurable are only strengthened by the author's admonition that expected costs and benefits over the life of the facilities should be compared.

Mr. Krutilla's analysis of the factors affecting the impact of a development program on a region, its effectiveness in increasing the supply of resources, and the characteristics of demand for these resources is certainly interesting, and his emphasis on the importance of demand for a region's output is thoroughly justified. But again I think the analysis is oversimplified. Clearly, the discovery and production of petroleum in Arabia has increased that country's resource supply functions, and oil is a product the demand for which is highly income elastic. Few, however, would argue that Arabia has been blessed with substantial development. Secondary industrial development has been almost totally absent. Certainly such matters as income distribution in the underdeveloped area, the propensity to invest locally, and other factors must be taken into account.

Description of industrial development in the area served by the TVA clearly indicates the tremendous significance of secondary or "triggered" developments, but Mr. Krutilla's rejection of aggregate series as tools for program appraisal leaves these developments to informal assessment. It occurs to me that the margin of error left by such a procedure is far wider than it need be and that it can be substantially reduced by careful use of income series.

Mr. Moore is highly successful in demonstrating that the input-output approach provides an interesting and useful skeleton for regional analysis and in doing so performs an extremely worth-while service. Too often, regional studies lack just such a skeleton. Too often, also, these studies suffer from the absence of reliable statistics, and the examination of Mr. Moore's model makes one wonder if perhaps his study does not put too much strain on the data. One cannot tell from the paper, for Mr. Moore merely confronts the reader with results—a regrettable but necessary procedure where the aim is primarily methodological and limits are imposed on length.

Devotees of this technique, I think, too often, because of persuasiveness and perhaps zeal, oversell their product. Unwary folk are trapped, failing to recognize the shortcomings and pitfalls, and look to input-output as the answer to any problem in economic method. Even if the basic data were accurate to the third decimal place, models based on this approach generally assume unchanging input coefficients. And such an assumption is more than hazardous, especially where many industries have excess capacity and when projections are made more than a very short distance into the future. Mr. Moore, in my judgment, shares this characteristic or failing with many "seasoned" input-outputers. A little more "seasoning" would perhaps not be amiss and might protect unwary regional researchers.

LEON N. MOSES: At the suggestion of this session's chairman, my comments will be restricted to Mr. Moore's paper. I shall attempt to evaluate what I conceive to be the author's two main contributions: his use of static input-output

procedures to develop a series of regional income multipliers for Utah and California; his dynamic input-output model for the state of California.

Mr. Moore's multipliers are supposed to provide an analytical tool by which "to measure quantitatively the effects on specific regional economies of given types of changes." Our evaluation of this tool will proceed in two stages. First, granted the assumptions, are Mr. Moore's multipliers based on a logically consistent model? Second, are the assumptions empirically justifiable? We may state at the outset that the author's static regional model—from which his multipliers are derived—falls short of adequacy on both counts.

There is very little discussion in Mr. Moore's present paper of how his regional income multipliers were obtained. In order to evaluate them properly, reference will be made to the author's Utah Study ("Regional Analysis: An Interindustry Model of Utah," November, 1953) which describes in detail the methodology behind these multipliers.

Mr. Moore's first step was the derivation of a gross transactions table for the state of Utah. This table shows the total purchases by each Utah industry of each good from all regions. It was obtained by multiplying known base period outputs by technical coefficients. However, the author's goal was an intraregional flow table; i.e., a table which showed the purchases by Utah industries of Utah output alone. This required that interregional and foreign trade be eliminated from the main body of the gross transactions table. To accomplish this the author first estimated Utah's final demand (household consumption, private investment, etc.) for each good. Utah's total consumption of each good was then obtained as the sum of intermediate or industrial demand and final demand. At this point, Mr. Moore assumed that his region would resort to imports only to satisfy requirements in excess of domestic capacity and that it would not export any good until domestic requirements were fully satisfied. This permitted him to "determine" imports and exports by subtracting total Utah consumption of each good from domestic production.

The gross transactions table could then be readily transformed into a table of intraregional flows. For industries in which Utah had a surplus, the amount of this surplus was entered in final demand as exports. In industries where Utah had a deficit, i.e., insufficient capacity to satisfy domestic requirements, the consumption by each Utah industry of these goods was reduced proportionately. The amount of the deficit was removed from the body of the gross transactions table and entered into the final demand sector as imports.

From the intraregional flow table thus obtained Mr. Moore derived a new coefficient matrix which we shall refer to as the regional input-output coefficient matrix. Each of its elements has a regional as well as a technical dimension. The coefficients in this matrix indicate the dollar volume which each Utah industry purchases from other Utah industries per unit of its own output. Our author computed the Leontief inverse of this matrix and used it to determine the impact on Utah's industries of changes in the final demand for Utah's goods. After determining the latter, the effect on Utah's income was calculated by multiplying each change in output by the corresponding household input coefficient and summing.

The appropriate question to ask at this point is whether Mr. Moore's re-

gional input-output coefficient matrix can logically be used to determine the impact of an increase in final demand? (We shall not deal explicity with decreases in final demand because the argument is quite similar.) The answer is that it cannot, unless his region has excess capacity in every line of activity. If even one sector has insufficient capacity in the base period, so that the region must resort to imports, then use of the regional coefficient matrix to compute the impact on Utah of a change in final demand involves a logical inconsistency. The reason for this is that the model will predict increases in the output of industries which are already operating at capacity. These increases are, of course, incorrect and—because of the interdependencies—the predicted increases in the outputs of all other industries must also be incorrect, as must the multipliers based on them.

Our discussion so far can perhaps be clarified by adopting a somewhat different approach. The major difficulty with Mr. Moore's static model is that the row elements of his intraregional coefficient matrix pertaining to industries of insufficient capacity are variables rather than structural constants. Their value is determined by the ratio of domestic capacity to total regional requirements of these goods. Since a change in any element of the coefficient matrix will—special circumstances aside—alter all elements in the inverse matrix, the latter is composed entirely of variables. Thus Mr. Moore's model and the multipliers derived from them do not provide a consistent method of estimating the impact on a region of changes in final demand.

The assumptions concerning imports and exports which underlie the intraregional flow and coefficient matrices are questionable. Given the degree of commodity aggregation used and the fact that Mr. Moore is dealing with a space rather than a point economy, it hardly seems reasonable to limit interregional trade to the disposal of net surpluses and the satisfaction of net deficits. Existing data on interregional commodity flows do not bear out Mr. Moore's assumptions. The above is only one aspect of the author's failure to give full recognition to the problems of regional interdependence. Another is his neglect of the "feed-back" effects; i.e., the impact which a region has on itself via its effect on other regions. Also, Mr. Moore has no way of determining what the impact on his region will be of changes in the final demands of other regions. He requires this as given data.

Lastly, the author himself comments on the fact that his multipliers may appear somewhat low. This is interesting, since they were computed in a novel way which exaggerates their size. Instead of forming a ratio between the ultimate increase in income and the increase in expenditure, as is usually done, Mr. Moore takes the ratio of the ultimate increase in income to the immediate increase. The latter is derived by multiplying the vector of changes in final demand by the vector of household input coefficients. The divisor of the latter ratio is smaller than that of the former, and the multipliers computed on this basis are therefore larger.

We have so far dealt only with the portion of Mr. Moore's paper devoted to static analysis. It is in the section of his paper devoted to dynamic questions that the author makes a significant contribution. The idea of combining dynamic input-output techniques with those of linear programing for determining

a maximum growth rate is both novel and interesting. However, in certain matters of detail the author could make improvements which would render his results more relevant and significant.

For example, Mr. Moore recognizes that a region can import a good rather than expand domestic capacity for its production and that it can reduce its need for additional capacity by cutting exports. Confronted with the difficult problem of specifying some optimum level of imports and exports, our author decided to assume them away entirely. By this device he destroyed the relevance of his work, since his problem became one of determining California's maximum growth rate under conditions of complete autarchy. This is unrealistic in the extreme when applied to an open economy. Moreover, if the region lacks capacity in any industry, then only a zero rate of growth is possible.

Mr. Moore has so far concentrated all of his attention on the limits to expansion imposed by existing plant and equipment. It would seem advisable to take into account explicity the limitations imposed by the nonreproducible factors—labor and natural resources—as well.

FRANK A. HANNA: So long as there are government programs which are either designed to influence the factors affecting regional output or which seek public support on the grounds that they have influenced these factors favorably, the problem of evaluating regional development programs is likely to be with us. Mr. Krutilla has done excellent service, first, in uncovering many of the pitfalls in the noncritical use of "regional comparisons of income relatives" and, second, in showing that specific development programs often may be evaluated more precisely in terms of their effects on a limited range of closely related activities than in terms of their effects on regional income, which presumably reflects all economic activity within a region.

With the rise in income in the southeastern states during the past two decades, it must have been very tempting to the supporters of TVA, to the state development commissions, and perhaps to other government agencies to point to this income rise as a sufficient justification of their programs. But knowing that income in an area has increased during a given period is not enough. We need also to know that it has increased more than would be indicated by some set of expectations that were derived from factors other than the "development programs." Typically, such a set of expectations is provided by the changes in national income. The income materials used are time series. Like most annual time series they are a mixture of secular trend, cyclical changes, and irregular or nonrepetitive changes. Somehow, from this mixture we have to extract secular trend. As both papers point out, it is only in terms of trend that changes in the underlying factors affecting regional output can be gauged. With present techniques, regional trends can only be approximated. At best, some of the irregular factors will remain, though in annual data these are likely to be small. Larger errors can arise from the imperfect exclusion of cyclical factors.

During the past two decades, the upward trend has been delayed only by the minor recession in 1937-38, the reconversion efforts of 1945-46, and

another minor recession in 1949-50. Nevertheless, cyclical forces have been present continuously. Since some industries are more sensitive to cyclical changes than others, the changes in a state's or area's income level for a given change in the national income may be expected to vary in accordance with the area's industrial composition. Rough estimates presented elsewhere (*Review of Economics and Statistics*, August, 1954) indicate that when the effects of national income changes and industrial composition are taken into account, each of the southeastern states, except Mississippi, has experienced an upward trend or favorable structural change, 1929-51. Krutilla's suggestion that individual industries be analyzed separately is also effective in eliminating cyclical influences if we can accept the very reasonable assumption that the cyclical forces associated with an industry on a national basis operate wherever the industry is found. However, when it is necessary to combine the trends for several industries, the question of appropriate weights becomes important. Use of the levels at either the beginning or the end of the period as area weights ignores differential growth of the industries. Moreover, the absolute levels of an industry in an area are the product of cyclical as well as secular forces. An industry's income, as a percentage of income originating, varies over the cycle as well as secularly. For the nation, this can be handled by averaging. But for a subarea, the averaging of relatives tends to confound cyclical and secular forces. To the extent that Mr. Moore's analysis is based on values rather than physical quantities, it suffers from the fact that the relationships he uses are based on one point in a cycle, 1947, and we might expect value relationships to vary over a cycle.

Mr. Krutilla takes a very pessimistic attitude toward the estimated error attaching to income estimates. No one knows what the errors in national income are. Consequently, they cannot assert that it is impossible for the regional distribution of errors to be as outlined in his extreme example. On the basis of what is known about the compilation of basic data, however, many would expect a more charitable distribution. The Morgenstern estimate of 10 per cent error, which he cites, is based on Kuznets' estimates in *National Income and Its Composition, 1919-38*. A careful reading of the original source shows that this is an estimate of the maximum error probable and that it applies only to the level of national income. The Commerce Department, in its *National Income, 1954 Edition* (page 66), recently stated that the levels "are subject to only a small percentage of error"—one gathers in the neighborhood of 1 to 2 per cent. There is room for larger errors in state income levels. But the error in the level tells us little about the error in the changes in national income or changes in regional income relatives. Would we not expect the errors of omission or commission in compiling the basic data used by income estimators to be of about the same magnitude each year? And would not the same errors be made in allocating income among regions? Even if the error component—the difference between the "true" and the estimated figures—behaved quite differently from the estimated figures, the error in the year-to-year changes from this source likely would be negligible.

I should now like to question whether the introduction of the "terms-of-trade" concept adds anything important to what is already provided by in-

dustry classification. Does a Midwest shoe factory have different terms of trade than a New England shoe factory? It is possible that it may have. It may, for example, be one of the sources of intraindustry dispersion in such measures as average production-worker earnings or value-added per employee. Certainly, industry could be expected to give rise to within terms-of-trade dispersion. Industrial composition seems to be highly correlated with income at the state level. If regional terms of trade are reflected by regional industrial composition, Occam's Razor would seem to indicate that we use existing industrial data rather than spending our efforts trying to create data suitable for terms-of-trade analyses. Agriculture may be an exception; primarily because little effort is made to classify farms even by the seven inadequate three-digit and four-digit categories provided in the *Standard Industrial Classification Manual*. Even in this important major group the provision of adequate categories and intensified efforts to classify farms in greater detail appear more promising than trying to analyze regional farm commodity production for the implied terms of trade.

Perhaps it is no accident that both Krutilla and Moore find their more promising techniques nationally oriented. Within a nation effectively without internal trade barriers, with a common monetary system, and with essentially similar legal and economic institutions, one might expect the income of subareas simply to reflect the industrial or occupational composition of the subarea. Indeed, on the basis of 1950 census data on occupations and on 1949 earnings, I have found that occupational composition accounts for about 80 per cent of the interstate differences in average annual earnings. With or without explicit development programs, subarea industrial compositions are undergoing constant adjustments to new economic conditions, either by selective contraction during periods of recession or by the development of new capacity during periods of full employment and national growth. Whether, at any particular moment, it is better to locate new capacity in subareas where resources are underemployed, as evidenced by low incomes, or to expect underemployed resources to seek higher incomes through migration will certainly vary by industry. By proposing to judge development programs which seek to affect this type of decision solely on the basis of the prospects and requirements of the relevant industries, Mr. Krutilla may have dampened some enthusiasm for regional programing, but he has also brought the problem into better focus.

URBANIZATION AND INDUSTRIALIZATION OF THE LABOR FORCE IN A DEVELOPING ECONOMY

LABOR ATTITUDES TOWARD INDUSTRIALIZATION IN UNDERDEVELOPED COUNTRIES

By WILBERT E. MOORE
Princeton University

In the literature on economic development a certain notable division between optimists and pessimists is apparent. This division is highly predictive of disciplinary origin. Economists—representatives of the "dismal science"—are customarily optimistic about economic growth and its social consequences. Anthropologists and sociologists are customarily pessimistic about the possibilities of economic growth and particularly about its consequences. Although possibly these fields attract different personality types—the manic and the depressed—it seems more likely that conventional theory and habits of thought explain the differences.

I. *Some Contrasting Theory*

Theory of Motives and Consequences. Traditional economic theory has not been strongly concerned with attitudes and motives. Human attitudes and motives are simply assumed to be appropriate to rational choice of means effective for maximizing satisfactions as economically defined and measured. Human wants are thought to be essentially unlimited and human nature pretty much the same wherever encountered. A monetary market system co-ordinates the factors of production and allocates rewards, and financial incentives are assumed to be effective in allocating labor. The movement of labor between sectors of the economy is regarded as a function of its differential marginal productivity, which is principally determined by relative states of capitalization, technique, and, possibly, enterprise.

Given these assumptions, such hints of pessimism that economists have about economic growth in undeveloped areas could be expected to center on questions of capital, market organization, and entrepreneurial activity, but not on the willingness of potential workers to work. And since the economist has a normal prejudice toward the view that improvements in levels of production and consumption are consistent with universal human aspirations, he is certainly inclined to optimism about the consequences of economic growth.

Anthropological and sociological theory stands in sharp contrast to this set of views. Attitudes and motives are of more central concern as variables, related to differential positions within any social system. The person is viewed as having been socialized in ways appropriate to differential social roles, to hold values appropriate to group activity and its survival, and to behave in ways that are "irrational" and "non-rational" as judged on economic grounds. Wants are thus viewed as limited and relative to social position. The social system is viewed as strongly resistent to change, in part because of secondary and tertiary consequences of changes in a complex functional network. If these considerations are important within societies, they are even more marked between them. To contrast with the economist's "similarity of human nature" assumption, the anthropologist or sociologist offers "cultural relativity." He is likely to emphasize differences in values and aspirations in space and time, and to be extremely reluctant to assume that Western experience can be used as a guide to behavior in Dahomey, Nepal, or even Peru.

Given these assumptions, such hints of optimism that anthropologists or sociologists have about economic growth in undeveloped areas could be expected to center on the adaptability of economic incentives and organization to traditional attitudes and patterns, and especially on the willingness of potential workers to work. And since the anthropologist-sociologist has a normal prejudice toward the view that bread or all purchasable goods and services are not enough to satisfy human values, he is certainly inclined to pessimism about the consequences of economic change.

These contrasts are, of course, moderately unfair to both professional groups. Many economists, and especially those who have studied labor mobility, the operation of labor markets, and worker behavior, have expressed strong misgivings about the assumptions of traditional theory. Many anthropologists and sociologists, and especially those who have studied the actual impact of modern economic forms in undeveloped areas, have noted the stresses and tensions in traditional systems and the considerable success of the new employment alternatives in recruiting labor.

Theory of Organized Co-operation. The literature on economic development has included very little material on another aspect of theory, on which our two professional groups tend to disagree. There are differing views on the nature of business and industrial organization as related to the attitudes or motives of participants.

Traditional economic theory has little to say on this subject, since labor is viewed as allocated by market mechanisms and the relation between employer and employee the same in principle as any other

economic contract. The productive efficiency of the division of labor has received consistent attention, but the problems associated with the authoritative co-ordination of labor implicit in factory organization remain relatively unexplored. Only in Marxist economic theory and, more recently, in attempts to construct alternative theories of the labor movement and management-union relations have variables such as power and group loyalties been considered.

Traditional anthropological and sociological theory also has little to say on business or industrial organization, partly because of a concentration on the structure of society generally, partly because economic organization was thought to be the proper province of economists. Only in Weberian sociological theory and, more recently, in attempts to treat "the factory as a social system" have variables such as the authority of office, communication systems, and "informal organization" been considered.

Despite the recent and still somewhat peripheral attention given industrial organization in the disciplines we have been comparing, some differences between the disciplines can be detected. There is a notable tendency for the economist to emphasize—and exaggerate—individual, competitive aspirations, and an equally notable tendency for the anthropologist or sociologist to emphasize—and exaggerate—group, co-operative aspirations. If the economist's model of behavior tends to be the prize fight, the sociologist's model tends to be the quilting bee.

II. *Some Empirical Evidence*

Faced with such contrasting views of economic behavior and its motivational sources, the analyst may be forgiven some confusion and permitted to seek refuge in the data. Unfortunately, evidence has not been collected or analyzed in ways that permit a clear resolution of theoretical disputes. It is possible, however, to get some leverage on the issues by reference to the reported experience in the recruitment and utilization of labor in undeveloped areas.[1]

Apathy and Opposition. A considerable body of evidence runs contrary to the notions that human wants are unlimited, that financial incentives will transfer labor from nonindustrial to industrial pursuits, and thus that the potential worker may be viewed as welcoming release from traditional restraints. Some of this evidence can be interpreted in terms of "rational conduct," but not in terms of economic maximization. The potential worker in undeveloped areas is typically required to give up traditional forms of organization and reciprocal obligations

[1] This section represents a selective summary of a rather extensive discussion, with citations to the literature, in Wilbert E. Moore, *Industrialization and Labor* (Cornell University Press, 1951).

that have combined to afford him security—both material and affective. The kinship system in any nonindustrial society is likely to provide a major barrier to individual mobility, because it is a social security system, because it is the focus of positive values and advantages, and because extended kin obligations are likely to reduce the effective appeal of individual rewards. With an extended kinship system, if the individual faces adversity, his kinsmen are obliged to come to his aid. If he prospers, he is obliged to share his good fortune with great uncles and second cousins once removed. Industrialization breaks up such units, by geographical separation and more importantly by social separation.

The other side of the coin (an inappropriate metaphor in its connotations) is the lack of appreciation of the new status system. This may take the form of a relatively low and highly particular appeal of wages, often commented on with reference to "native" laborers, but also commented on by preclassical writers in economic theory with reference to workers in the early stages of the Industrial Revolution. The principle bears extension, however. New occupations simply do not fit traditional standards of prestige, or are valued negatively because they involve manual labor and merit placement irrespective of age, kinship position, caste, or other forms of "ascribed" status. To the extent that the potential worker operates as an independent producer, the change to wage labor involves some loss of "freedom," even if it offers higher rewards. To the extent that the potential worker operates as the equivalent of a craftsman, the change to factory employment is likely to involve a loss of socially recognized skills, of "workmanship," in the division of labor and its subordination to machine processes.

It would be hard to deny that a considerable part of this apathy and opposition is "reasonable," but equally hard to deny that its explanation lies partly in social standards and values that are badly served by wage incentives and by industrial forms of labor allocation.

The Force of Circumstances. If wages have a limited appeal to nonindustrial populations and new employments are negatively valued, it is not surprising that workers are more commonly "pushed" than "pulled" into modern forms of economic activity. Much of the "push" is in fact the largely unintentional consequence of external intervention. The successful attempt to reduce mortality has the effect of deteriorating man-land ratios, thus increasing agricultural underemployment and causing the landless and impoverished rural dweller to seek and accept other means of livelihood. The introduction of cheap manufactured goods may well displace the handicraft worker and make available an additional pool of workers, either directly or through increased dependency on agriculture. Even the trader may be displaced by large-

scale distribution, or simply by more efficient organization of established markets.

The coercion of hunger does not exhaust the available pressures. Direct political coercion also has an extensive record, ranging from forced labor to the indirect coercion of taxation—a system which has been widely used as a device in colonial Africa.

Not all of the sources of pressure on the potential worker are so clearly external in origin. Any society exhibits some degree of tension and strain, some evidence of dissatisfaction. The presence of new alternatives may allow the deviant who seeks to evade the sanctions of the traditional order to escape from unwanted and oppressive controls.

Again it would be hard to deny that the attitudes implicit in these types of behavior are reasonable and again equally hard to deny that they do not correspond to notions of high sensitivity to slight differences in incentives and opportunity.

The Efficacy of Positive Inducements. Not all of the empirical evidence involves such negative attitudes toward industrial labor. Wages do have an appeal, particularly if they can be used for goods and services that form part of traditional patterns of consumption and traditional modes of relationship. The transitional forms are many, and often oddly at variance with Western conceptions of market operation. The African from the native reserve who works long enough in the mines to pay his hut tax is presumably not highly integrated into a market system. He becomes slightly more integrated when he uses wages to buy cattle for use as a bride price, but this still has a distinctly exotic flavor. His behavior fits our standard conceptions better when he proves interested in all sorts of commercialized goods and services, but of course by then he is likely to have little in common with the values of the preindustrial community.

In some places other inducements to work seem to have operated, although not necessarily in the absence of financial incentives or contrary to their economically expected effect. Patriotic motives and other collective goals have formed the basis of appeals to workers in most industrial societies, with what effect it is difficult to say precisely. Certainly it is likely that a sense of voluntary participation in a worthwhile common enterprise offers some source of satisfaction to workers, although the standard forms of productive organization are not well adapted to making the use of such appeals very convincing. Here, it may be noted, is a possible positive role for union-type organization. Certainly the communists have attempted to involve workers in undeveloped areas in the organized building of the new as well as the destroying of the old forms of social allegiance and power.

III. *Toward a Tenable Theory*

The discussion to this point implies the rejection of two extreme theoretical positions, both of which constitute alternatives available in the literature. The one extreme may be attributed to economics, although by no means all economists would subscribe. To traditional economists, labor attitudes are simply unproblematical, as they are adequately subsumed under the assumptions of maximizing want satisfactions. The other extreme may be attributed to anthropology, in the same unrepresentative sense. To the anthropologist labor attitudes are so problematical, because they are so conditioned by variable cultures, that no other general statement about them is possible.

The attempt to formulate here the elements of a low-order theory rests upon the assumption that it is possible to give a general characterization to the undeveloped areas, to specify some of the crucial characteristics of modern economic organization, and to indicate some of the labor attitudes which are significant for transition from one to the other.

The Nature of Undeveloped Areas. Although it is true that cultures differ, and in many ways, it is possible at a higher level of generalization to detect common and essential functions in the organization of society. Every society has provisions and rules for reproduction, socialization of the young, production and allocation of goods and services, adjustment to the nonhuman environment, maintenance of order. It is also possible to detect some common bases in cognitive orientations and values. All societies encourage some material aspirations (although not necessarily expanding and competitive), some rational, technical orientation to the use of the environment (although not necessarily innovative), and some positive value on health and length of life.

There are internal sources of tension and strain in all societies. The model of the perfectly integrated society is a useful analytical fiction for many purposes but ought not to be confused with primitive or agrarian societies. The sources of strain include, at least, uncertainties in socialization from generation to generation, chance innovations, and competing role demands given scarcities of time, treasure, and energy (or affective loyalty).

All undeveloped areas have already been disrupted in some form and degree by the "external" influence of Western patterns. The consequences of this interference may or may not be favorable to continuous economic development, but this will depend in some measure on the strategy adopted in view of the situation, as well as on the probable effects of influences so far.

One negative generalization is also negative in its implications for

labor attitudes toward industrialization. Mobility on the basis of individual performance is generally not markedly present in undeveloped areas and does not generally form a part of the positive value system. Whether for the individual or for the system as a whole, continuity and not change is likely to be the major value.

The Nature of Modern Economic Organization. It is now commonly recognized that modern economic enterprise depends upon a complex institutional structure. For purposes of simplification this may be partially summarized as a monetary-market mechanism for allocation of the factors of production and for achieving distribution of goods and services. For the nonhuman factors of production this involves at least transferable property rights and rational cost accounting. For the human factors of production this involves a wage system for putting into the hands of the specialized worker a medium for commanding the necessary and appropriate goods and services for himself and his dependents.

Although part of the division of labor will be co-ordinated by impersonal market mechanisms, the fixed capital and economies of scale in the productive unit characteristic of industrial organization imply also administrative co-ordination and the development of scales of authority.

If labor is to be rationally allocated and optimally utilized, it appears essential to select on the basis of technical competence, to co-ordinate on the basis of relationships specific to the interdependent tasks, and to tie rewards to types of activities. These rewards need not be exclusively financial and indeed rarely will be. All of the rewards imply a system of social ranking closely related to position in the productive system.

The Nature of the Transition. Whether one looks at undeveloped areas or the most highly industrialized ones, a fundamental theoretical point is evident. That point is the great complexity of human motivation. Men will work for as many reasons as there are values to be served by such activity and will refuse to work where that serves his values. The fact that industrial systems emphasize values that are commanded in a market and incentives that provide monetary claims on a market should not blind us to the diversity of ends or the diversity of means for their satisfaction.

The effectiveness of wage incentives is relative to the availability of goods and services in the market that form part of the effective wants of workers. This is essentially a common-sense static principle. But it is quite limiting, and failure to recognize it accounts for some of the exasperation of observers of "irrational" natives. The worker in an undeveloped area is typically not accustomed to expect, or even to aspire to, any considerable raising of ceilings on his consumption and

social position. And there are many wants typically not satisfiable by market mechanisms. So we have both limited demand and limited supply.

To translate this principle into dynamic terms, the available evidence indicates that we should expect an increase in demand through knowledge, education, and the development of new values, and in supply through the addition of goods newly available because of industrialization and the movement of services into the market.

This view of market-oriented attitudes can be broadened, with considerable benefit to its theoretical importance.

The effectiveness of the appeal of new employment alternatives is relative to the availability of need-satisfying rewards. This principle will still apply if material or even financial well-being is held constant. The potential rewards include prestige and esteem within an acceptable system of social valuation. This also is a common-sense static principle and is also limiting. The traditional system of social valuation will not typically include the new activities, and the latter compete or conflict with the former. Both change and choice tend to be devalued. If some relationship between wages and markets has been established, higher wage levels can be used as a principal lever on conservative traditions, and this has been their historic role. The private employer is unlikely to act "correctly" in this matter, and this may be a major area for governmental policy in economic development.

Over time, we should expect an increase in aspiration and the addition of values associated with status mobility, merit evaluation, and a realistic sense of choice and initiative. We should also expect new systems of social organization and stratification to which these aspirations and values are appropriate.

Economic growth, insofar as it is affected by labor attitudes, is likely to be radically retarded or contained by any one of several vicious circles. There is considerable evidence of a reciprocal relationship between low wages and low productivity, whether the connection works through mere physical energy or through more subtle frustration and apathy. The failure to detect and utilize convertible craft skills, the assumption that initially unskilled local labor is incapable of training, and the adoption of the "color bar" as an extreme and open manifestation of these practices constitute waste in the short run and possible failure of continued development in the long run.

It appears evident that neither the available skills nor the appropriate attitudes can be assumed to be adequate among the potential workers in undeveloped areas. Growth seems to have been most rapid and most probably continuous in the future where considerable resources have been devoted to formal education and where education and in-service

training have been most closely geared to the skill demands of an industrial economy. Now, clearly, education in many colonial areas has encouraged anything but the development of mechancial and technical skills, and the opportunities for use of any such skills have not been made available to natives. That the new native leaders tend to be political agitators rather than economic administrators is scarcely surprising in view of colonial political and economic policies.

The development of positive labor attitudes toward industrialization would probably be enhanced by the fostering of a sense of social participation as well as by the expansion of individual opportunity and the provision of amenities and security at least equivalent to those available in traditional organization. A sense of social participation has been consistently neglected even in advanced industrial societies. We do not know how flexible industrial organization may be made. But if economic development entails a revolutionary change in the organization of society, as it does, there is at least some theoretical reason for supposing that workers as well as managers or government officials might welcome positive participation in partial compensation for their uprooting.

In view of the complex richness of human motivation, the idea that economic and noneconomic incentives are necessarily competitive for a limited supply is untenable. Both may be increased simultaneously and continuously within very high limits.

IV. *A Methodological Note*

The reason for our interest in attitudes toward industrialization is clear and simple: we want to predict behavior relevant to the industrial mode of production. In stable situations the best predictor of behavior is previous behavior, and attitudes become "intervening variables" in the strict sense. That is, attitudes are necessary but inferential phenomena required to explain the mechanism of action to answer the motivational "Why?"

To predict behavior in novel situations we are likely to want to attach greater significance to attitudes as prime variables. Attitudes may be defined as those psychological attributes of the individual which determine his tendencies to act in specified ways in specified situations. Such tendencies to act involve both a cognitive "definition of the situation" and an affective "evaluation of the situation." Any behavior we are likely to be interested in necessarily involves affective or evaluative components—at the very least, ends and criteria of choice.

Since attitudes are not directly observable phenomena, but some such variable is theoretically required, we are faced with some nasty methodological problems. We infer attitudes from behavior, including

verbal behavior but not excluding other behavior. It is not necessarily true that verbal statements of attitudes are more reliable predictors than are previous relevant actions, if known. The reliability of attitude measures in forecasting subsequent behavior is rather low. But since representative samples of action are often difficult to observe, considerations of convenience lead many social scientists to rely on interview data. If the behavior to be predicted is itself novel, such as reactions to new modes of employment, we are likely to want several indexes of attitudes in the hope of increasing our probabilities. Given a population with some relevant knowledge and experience, personal or vicarious, it is possible that attitudes can be uncovered by techniques ranging from direct questions to projective tests. At best, we are relying on the human characteristics of generalization, transfer of learning, and transfer of values as ways of indicating probable reactions to new situations.

Asking direct questions is, of course, not the only recourse, but it is one appropriate partial procedure. The alternatives, which underlie most of the allegations in this paper, include extrapolation from "comparable" situations at other times and places, and "pure" functional analysis for locating types and degrees of vested interests, sources of tension and strain, and opportunistic and disgruntled elements in the preindustrial situation. Any prediction from any available procedure is somewhat hazardous, for experience is still the best teacher of social scientists, as it is of men.

THE CITY, THE FACTORY, AND ECONOMIC GROWTH

By Bert F. Hoselitz
University of Chicago

I

In a generally accepted view, the economic development of underdeveloped countries is contingent upon the introduction of industry. Industrialization, in turn, is associated with urban growth, and the relationship of these two processes is usually assumed to be so close that some writers speak of industrialization and urbanization as two facets of one and the same process.[1] The evidence for the need for industrialization and urbanization is found in the historical experience of the economically more advanced countries and in general considerations on the economic situation of the farm populations in many underdeveloped countries.

The advanced countries contain the most heavily industrialized and at the same time most densely urbanized regions of the world, and to the extent to which industrial cities have grown up in underdeveloped countries, they have been patterned after British, German, and American models.

The improvement in the economic position of subsistence farmers who make up two-thirds or more of the people in many underdeveloped countries is dependent upon industrialization. There are scarcely any underdeveloped countries in which there is not a large surplus of unemployed agricultural labor. This surplus farm labor represents a tremendous waste of human resources and the obvious remedy is the transfer of these "redundant" persons into industry. But their removal from the farms may not always be sufficient and may have to be implemented by removal from the villages to urban areas.

We may conclude, therefore, that industrialization and urbanization are effective means for economic advancement. But this process is not one of unmixed blessings. The social consequences of the growth of industrial urban centers in underdeveloped countries are well summarized by Motwani, when he describes the cities of South Asia as "huge mausoleums of coal, smoke, iron and steel, of dirt and squalor, of overcrowding, of cooly-lines, and human warehouses. Long hours, low wages, bad housing, woman and child labor, infant mortality, accidents, high rents, poor sanitation, prostitution, gambling, racing, dope dealing,

[1] See for example, Kewal Motwani, "The Impact of Modern Technology on the Social Structure of South Asia," *International Social Science Bulletin*, Winter, 1951

dance halls, cabarets and night clubs were features of all the cities. The noise corroded the nerves of the city dwellers, while absence of neighborhood restricted their social contacts and made them strangers to each other." *(Op. cit.,* page 787.)

Much of this is true. But many of Motwani's charges are not the consequences of the growth of cities but rather of general conditions of economic backwardness and poverty. His reproach against urbanization and industrialization is too undifferentiated to be fully effective. Infant mortality is much higher in the rural areas of underdeveloped countries than in their cities; the standards of housing are also, on the whole, rather better in cities; and many of the rural laborers work long hours and receive pitifully low incomes for their toil. Normally the small subsistence farmer works harder and gets less than the factory worker or the workers on plantations, mines, and railways.

But although industrialization and urbanization go usually hand in hand, there is no necessary connection between the two processes. Industries can be and have been established in rural districts and cities have grown up without large industrial plants. The introduction of new technology may sometimes change existing social relations very little and sometimes subvert them completely. The social relations created by modern factory organization, implying new hierarchial relations in the work situation, discipline, the dependence of the worker upon a money wage, the uncertainties and insecurities connected with the proletarian style of life, are not peculiar to urban industry. These same conditions hold in plantations and mines which are typically located in rural surroundings, on railways and other means of transportation, and communication which stretch far out into the countryside. The almost automatic association of industrialization with the introduction of the factory system as it was practiced in the mid-nineteenth century made us forget that the advantages and disadvantages of technological change in underdeveloped countries may be attributed to different factors and that the relative contribution of each of these factors in the over-all process of economic development and technological change must be more clearly determined in order to provide guiding principles for developmental planning. For if certain "undesirable" outcomes can be associated with one factor alone, it may be possible to plan in such a way as to eliminate or at least mitigate the incidence of the undesirable outcome.

In order to isolate the impact of industrialization from that of urbanization, we will examine each of these processes separately. In the subsequent discussion the contrasts and differences will appear sharper than they are in reality. By describing situations which approximate

ideal types, some of the variables are placed in greater prominence than if an attempt is made to present a fully realistic description with all shades and qualifications. I do not maintain that the sharp contrasts which will appear in the discussion are necessarily present in all the developments described. They are emphasized here because by this method attention is drawn to the most important tendencies accompanying industrialization and urbanization in a developing economy.

II

Let us begin with the analysis of "industrial" cities. Firstly, they are new, not merely in the sense that most of them are the product of urban growth of the last 150 years, but rather that many industrial cities arose in places where earlier there had been no places of settlement at all or only small villages or hamlets. Manchester, which has been called the "first industrial city," was described by Daniel Defoe in 1727, as a "mere village." (Daniel Defoe, *A Plan of the English Commerce* [reprint ed.; Oxford, 1928], page 64.) Also other heavily industrialized areas of Great Britain—the Glasgow region, the Newcastle region, the Rhondda Valley, and parts of the Black country—were wasteland or farmland with few and unimportant settlements up to the middle of the eighteenth century. Extensive evidence for the rural character of the Ruhr Valley at the beginning of the nineteenth century was collected by Pierre Bernaerts. He cites accounts of the time which state that the Westphalian region in the 1830's presented "the character of an agricultural country with a few market towns which also had some handicraft trades. No contemporary document envisages by any means the extraordinary upheaval which, in the course of one generation, was to bring forth in this territory the most extensive industrial region of the European continent. . . . Essen is described as an agreeable small town . . . in which in summer the cows were taken to the communal grazing grounds. . . . Oberhausen, Gelsenkirchen and Ruhrort were tiny dots on the map." (Pierre Benaerts, *Les origines de la grande industrie allemande* [Paris, 1933], pages 101-102.) It is superfluous to point out that the great industrial metropolitan centers in the United States, Canada, and Australia grew in places where not even villages had been before the first settlers decided to build their cities in these spots.

The newness of the industrial city—the absence of a long urban tradition with guilds and market privileges and other vested interests—was doubtless an important factor in their rapid rise. Although urban growth in England was rapid everywhere during the nineteenth century, the new cities grew faster and ultimately reached larger size than the older cities. Manchester outstripped Birmingham and Leeds, the cotton

towns of Lancashire overtook the woolen towns of Yorkshire, the coal towns and the iron towns of the north and west overtook the commercial and small-industry centers of southern and eastern England.[2] But although the new cities did not have deep historical roots, they grew up in a cultural environment in which there existed a long urban tradition. They adopted and modified the old institutions, but there was never any question that each of these rapidly growing entities formed a "corporation," a whole of some sort, that the inhabitants of the city were the members of one and the same community, and that they had rights and privileges in the community and duties towards it. Classical liberalism at its height saw some experiments in municipal "socialism" in such fields as sanitary provisions, street lighting, gas and water works, and other services. Municipalities entered the field of education and culture: they built libraries and schools and recreation grounds and parks. In spite of the intense ego-orientation stimulated by classical liberalism in the economic sphere, the older collectivity-oriented values prevailed even in Cobden's Manchester. In spite of slums and low housing and sanitary standards in many parts of the industrial cities, the whole city formed a community. It was not merely altruism or beneficent self-interest which made some municipal reformers agitate for slum clearance and municipal improvement. An important role was played by the sentiment of community; i.e., the conception that any blemish in the city's landscape was a matter of concern for all its citizens.

This sentiment of community became concretized in at least two institutions and types of attitude which persisted thoughout the Western world. One was the tradition of self-government—of the city's taking care of its own present and evolving needs. This found expression in at least some political consciousness and activity of most of the city's inhabitants. The vigorous development of municipal self-government and public services in all Western cities is largely an outflow of this tradition, although it developed different forms in different localities. Secondly there persisted, also, even if in a changing and transformed way, the attachment of the city's population to the urban way of life. This became manifest on the one hand in the clearer distinction between city and country and the city-dwellers' self-consciousness of the differences in their attitudes and objectives from those of the countryside. On the other hand, it showed itself in the development of functionally specific areas in the city itself. The concentric arrangement of modern industrial cities, with their central business districts and their changing belts of industrial and residential areas, the location and function of

[2] On the differential growth of British cities in the nineteenth century, see the forthcoming article by Eric Lampard, "The History of Cities in Economically Advanced Areas," *Economic Development and Cultural Change* (January, 1955), pp 111-112.

district shopping centers, the pattern of intracity communications, and many other features of a similar kind, show the interdependence of all parts of a city upon one another and are proof of the over-all unity of the urban community in spite of its internal wide diversity.

A second common characteristic of the industrial cities in the advanced countries is that their growth was by and large associated with the demand for labor and that people moved to the cities because employment opportunities existed there. This process was made possible by the often rapid growth of industrial investment in the city. Let us again take the example of Manchester, which exhibits this pattern clearly. In 1780 only one factory, that of Richard Arkwright, could be found within the perimeter of Manchester; in 1790 the first Bolton and Watt steam engine was installed in a cotton mill; and by 1820 there were sixty-six cotton, six silk, and six woolen spinning mills in Manchester. By that time factory spinning became unprofitable unless combined with weaving. As a consequence, the manufacturing capitalists were obliged to install the improved power loom and to integrate the spinning, weaving, and finishing processes in one single establishment, each of which employed between three hundred and a thousand workers. By 1845 there were more than a hundred integrated factories in Manchester and Salford. But in addition to this growth of the cotton industry, subsidiary industries were progressing. Machine makers, forges, tin plating establishments, leather workers, braziers, harness makers, as well as railways, canals, breweries, and chemical industries, were clustering around the cotton mills of Manchester and Salford. This expanding concentration of industry called forth a secularly ever increasing demand for labor.[3] As a city grew in population and as subsidiary production developed around each city's main specialized industrial branches, external economies for these main industries increased. Anyone newly establishing a cotton mill in Manchester could count not only on the presence of a skilled and disciplined labor force, but he had suppliers of raw materials, wholesalers to whom he could easily sell his output, sources of credit, repair shops for his machinery, and many other subsidiary services near at hand. This in turn encouraged the further expansion of the industrial base of the city and called for further increase in employment opportunities and a growing demand for labor.

A third characteristic of the industrial city in economically advanced countries is the role it plays in the process of cultural change. Robert Redfield and Milton B. Singer distinguished two phases of cultural change which are mediated primarily by urban centers ("The Cultural

[3] Leon S. Marshall, "The Emergence of the First Industrial City: Manchester, 1780-1850," in Caroline F. Ware, *The Cultural Approach to History* (New York, 1940), pp. 140-143.

Role of Cities," *Economic Development and Cultural Change,* October, 1953, page 59). One is the phase of "orthogenetic" and the other of "heterogenetic" cultural transformation. By orthogenetic cultural transformation Redfield and Singer mean the development of a great tradition, such as took place in the cities of ancient Egypt, China, Mayan Yucatan, and the Christian centers of the European middle ages. Heterogenetic cultural transformation, on the other hand, is a process in which acculturation—the absorption of new culture elements from the outside—takes place and in which predominantly rationalistic tendencies prevail. It is obvious that the growth of the industrial city is a process of heterogenetic cultural transformation. But the industrial cities were not the spearheads in this process but latecomers. The phase of heterogenetic transformation of Occidental cities began with the end of the middle ages, and the "spirit of capitalism" and of rationality were well developed and fully accepted into the pattern of Western social values when the rise of the industrial city began. In other words, the growth of industrial cities took place in a cultural climate favorable to the further development of the technical order in which the modern industrial city could flourish. The industrial city, in turn, soon became one of the chief centers of social change and played an important role in strengthening the new technical order based on rational allocation of resources, competitive markets, and the pursuit of self-interest in economic action.

This development in the value system of the modern world, of which the industrial city is one of the most characteristic symbols, has sometimes been expressed by stressing the presence of universalist, achievement-oriented norms, as against the predominance of particularistic, ascription-oriented norms in less developed societies.[4] This transition in value structures is accompanied by stresses and strains which tend to produce features of social disorganization in various degree. The impact of the modern industrial city, as a latecomer in this transformation process, made itself felt at a time when the basic alteration in social values had already been achieved and its main role has been to reinforce an already existing system of social values rather than to participate in the creation of new ones. Although the industrial cities of the Western countries have witnessed episodes of severe social disorganization, they have been able to overcome these disruptive

[4] The original definition of these variables was given by Talcott Parsons, *The Social System* (Glencoe, 1951), pp. 58 ff. They were applied to the analysis of economic growth in general by Bert F. Hoselitz, "Social Structure and Economic Growth," *Economia Internazionale,* August, 1953, pp. 52-72. The same conceptual scheme was applied to the analysis of the modern industrial city by William L. Kolb, "The Social Structure and Function of Cities," *Economic Development and Cultural Change* (October, 1954), pp. 30-46

tendencies better because they were not places of cultural innovation but rather of cultural consolidation.

III

Before examining to what extent the origins of industrial cities in the underdeveloped countries differ from those of Western industrial cities, we must take a look at one group of Western cities which have performed chiefly other functions than specialization in given branches of industrial production or the supply of specified services. These cities are usually referred to as "central cities."[5] The most characteristic central cities are the capitals of some European countries; for example, Paris or London. They are not only political and cultural centers of their respective countries but also perform some of the central economic functions in the national economies. The money markets, often the transactions with foreign countries, the main wholesale and retail houses, and several important industrial and manufacturing branches are concentrated in these cities.

The history and role of central cities differ markedly from the industrial cities. Central cities—even central cities of only provincial importance—are on the whole older than industrial cities. They developed out of towns which had some political importance already in medieval times, and many of them have tended to perform "central city functions" for a considerable period of their history. Economic growth has been more halting in them, traditions have lingered longer, and their influence has often been on the conservative side. Although some capitals grew as rapidly as some industrial cities, many provincial central cities developed much more slowly.[6] They resisted industrialization more effectively than the newer cities and the influx of migrants into these central cities was motivated not always by search for employment or economic betterment but by expectations of political promotion, or simply the desire to be on the scene where important new events were taking place. The general transformation in the value system has affected the central cities as well as the industrial cities. But in the former the raw edges were somewhat smoothed, extremes were, on the whole, avoided, and the impact of the new economic ethic was less drastic. It is probably no accident that the economic ethic extolling universalist, achievement-oriented norms is referred to as "Manchesterism" and that American sociologists have chosen Chicago

[5] Edward L. Ullman, "A Theory of Location for Cities," in Paul K. Hatt and Albert J. Reiss (ed.), *Reader in Urban Sociology* (Glencoe, 1951), pp. 123-132.

[6] On the different ranks of central cities see especially Walter Christaller, *Die zentralen Orte in Sueddeutschland* (Jena, 1935), and Ullman's discussion of Christaller's schema, *op. cit.*, pp. 126-127.

as the model when they wished to describe the specific flavor of the sprawling, big, American industrial metropolis.

IV

If we now compare industrial and central cities in the underdeveloped countries with their counterparts in the advanced countries, we find several rather startling differences. Above all, there are hardly any genuine industrial cities in underdeveloped countries. Though the absolute number of cities with population 100,000 and above is as large in "preindustrial" countries as it is in industrial countries, the very fact that in the former set of countries more than half the males are occupied in agriculture, fishing, or forestry explains the scarcity of genuine industrial cities in these countries.[7] Though such cities as Kanpur or Ahmedabad in India, Maracaibo or Monterrey in Latin America, and Dharan in the Middle East may be regarded as genuine industrial cities, the majority of the cities of underdeveloped countries perform numerous central city functions and industry plays often only a relatively subordinate role. Thus, if Motwani designates the cities in underdeveloped countries as "mausoleums of coal smoke, iron and steel," he can speak only of very few such cities, and even there of relatively limited quarters only. The appropriate counterpart for comparisons with cities in underdeveloped countries is, therefore, not the industrial cities, but the central cities of the advanced countries. But the central cities have shown themselves more stable and more resistant against the introduction of new values. They have resisted, also, to some extent the introduction of industry. They have had fewer upheavals, there was less disorganization, and there was maintained a higher degree and more profound sense of collectivity-orientation than in the industrial cities of the advanced countries. It is the contrast between places like Toulouse, Munich, Edinburgh, or Albany—cities with important central city functions and fair degree of industrialization —and centers such as Dakar, Djakarta, or Mexico which comes under scrutiny.

If we trace the actual origins of the cities in underdeveloped countries, we find that many of them, like the bulk of the industrial cities of Europe and North America, are new. They were founded by foreign traders or invaders; in the colonial and excolonial countries, by representatives of the colonizing power. Some of the cities in underdeveloped

[7] Kingsley Davis and Hilda Hertz Golden have shown in the article, "Urbanization and the Development of Pre-Industrial Areas," *Economic Development and Cultural Change* (October, 1953), p. 9, that of the world's 807 cities with populations of more than 100,000 persons, 463 are located in countries with more than half the occupied males in agriculture and 434 in other countries. The total population of the first group of cities is roughly 160 million; that of the second group, only approximately 155 million.

countries are planted upon the native cities which existed previous to contact with the West. These last cities—places like Mandalay or Benares, Mecca or Fez—have shown most refractory against change and the introduction of industry. They often played an important role in the orthogenetic transformation of the urban culture of the underdeveloped country; they were "sacred" cities in which important traditions of the cultural past of these countries were preserved. They have resisted the introduction of new values and new methods and the Westerners found it often easier to leave these cities as oases of "backwardness and superstition" and to construct their own cities elsewhere. This experience has been made also in tropical Africa. The relatively large settlements of indigenous peoples which existed before the full penetration of parts of West Africa by Europeans appeared to be ideal sites for the establishment of commercial and industrial activities by the colonizing powers. Often these settlements (as for example some of the larger towns of the Yoruba in Nigeria) were situated on favorable spots on rivers or in sheltered bays. There was a large population nearby which offered a potential ample labor supply and housing of a sort already existed in the native town. Hence these towns appeared, on the surface, as the most promising places for economic development. But it was soon found that the very existence of a previous settlement, with all the customs and beliefs which had developed in it and around it, proved a very unsuitable place for rapid change. There were serious rigidities, even revolts. The generalization that a city is, in general, the readiest place for innovation proved fallacious with respect to these towns. The most rapidly growing and most "Westernized" settlements in Africa were not the places with a long urban history but the recent creations of the Europeans.[8] Thus many cities—even in countries with old cultures—are new and, in addition, creations of outsiders. Balandier says of West and Central Africa (an area with considerable urban traditions) that the only city "which has risen to the scale of a great European town" is Ibadan in Yorubaland, Nigeria (*op. cit.*, pages 3-4). All the other cities were founded and built by whites, although they are inhabited predominantly by Negroes.

It is, therefore, not surprising that in African cities a sense of community, as we know it in Western cities, is absent. This does not mean that Africans are not collectivity-oriented. On the contrary, they are

[8] On urbanization in Africa, see the Working Papers submitted at the Conference of Social Scientists on the Social Impact of Industrialization and Urban Conditions in Africa, held from September 29 to October 7, 1954, at Abidjan, Ivory Coast, under the auspices of UNESCO. Cf. especially the papers by Rhona Sofer, "Adaptation Problems for the African Population in a Society of Early Industrialization at Jinja, Uganda," and by Georges Balandier, "Urbanism in West and Central Africa: Suggested Trends of Research" (mimeographed).

more deeply tied to the group to which they feel they belong than Westerners. But the group to which the African is loyal is not the city in which he lives, but his family, his kin, his tribe, his village. African cities are, therefore, collections of many separate compounds. This characteristic of the African city is confirmed by the all too few social surveys which have been made in Africa. For example, Mrs. Sofer writes that the African population of Jinja is heterogeneous and variable (*op. cit.*, page 1), and Balandier prefers to speak of "les Brazzavilles noires," indicating that the various African quarters of Brazzaville are as many separate towns *(op. cit., passim)*. This lack of unity in urban agglomerations is found also in other underdeveloped countries. Redfield describes Mérida of 75 years ago and shows that by that time the various *barrios* formed virtually self-contained independent villages. Though some integration has taken place since that time, many particularistic features still prevail. Pierre George discusses the *bidonvilles* of the cities of French North Africa, and finds there also a high degree of particularism. Finally, and most importantly, the lack of internal cohesion and unity has been found to be characteristic of the cities of India, Burma, Thailand, and Indonesia. In fact in some Indian cities it appears to be so pronounced that some students believe this trend towards particularism to be a lasting feature of Indian urban development.[9]

One of the great contrasts between the cities of the underdeveloped countries and those of the West is therefore the absence of a "city-consciouness" in Asia and Africa and perhaps also in Latin America. This implies, at the same time, that the distance between urban and rural styles of life is less pronounced than in Europe; that the loyalties of the urban dwellers are frequently to groups whose center of gravity is outside the city; that sojourn in the city is regarded often as only temporary; that migrants to the city from one village or province not only tend to settle in clusters of their own but that even when they have become permanent city dwellers they maintain some ties with the region they came from; and that each district of the city forms a community of its own, often rigorously separated from the others. These differences have already been pointed out almost twenty-five years ago by Max Weber. He examined the pecularities of Chinese, Indian, and Arabic cities and concluded that "only the West has known an urban community [*Stadtgemeinde*] in the true sense of the word as a mass

[9] See Robert Redfield, *The Folk Culture of Yucatan* (Chicago, 1941), pp. 25-28; Pierre George, "Bidonvilles, a Form of Urban Development in Underdeveloped Countries" (lecture presented at the International Conference on Underdeveloped Areas at Milan, October 10-15, 1954); McKim Marriott, "Some Comments on William L. Kolb's 'The Structure and Function of Cities,' in the Light of India's Urbanization," *Economic Development and Cultural Change* (October, 1954), pp. 51-52.

phenomenon." (*Wirtschaft und Gesellschaft* [3rd ed.; Tübingen, 1947], Vol. II, pages 523-528, especially 523.)

The consequences of this fact are of considerable gravity. Most of the European migrants to the cities in the eighteenth and nineteenth centuries came from the countryside, just as the migrants to cities in underdeveloped countries today. But whereas the European, once he had reached the city and lived there for a short time was able to cut himself loose from his old home because he found a new home with new loyalties in the city, the Asian or African does not experience such a transfer of loyalty. He continues to "belong" to the place whence he came and he never feels fully and exclusively at home in the city. The migrant to the city in underdeveloped countries lives in a strange and foreign place as long as he remains in the city and this alone increases the psychological stress he experiences. It means, also, that he seeks as associates only persons who come from the same kinship group, village, or province as he himself. In this way almost all interpersonal relations into which he enters are strongly influenced by the pattern of group formation peculiar to his native culture. He works with men who have the same ethnic and often even the same local origin. He lives in a social structure in which authority and responsibility are distributed according to patterns characteristic of his native culture rather than that of the city and its economic needs. His relationships with his fellow-workers, his supervisors on the job, his trade-union—if he is a member of one—are expressions of the culture and social structure of his native environment and not of the city or even of the European model after which they were patterned. It is therefore not surprising that we find among the noncommunist union leaders in South Asian countries two groups, one of which "consists of leaders whose authority is local and based on native traditions" and the other of which, though inspired by Western models, tends to "resort to autocratic measures, making it hardly distinguishable from traditional forms of leadership, except perhaps in its professed ultimate objectives." (George E. Lichtblau, "The Politics of Trade Union Leadership in Southern Asia," *World Politics*, October, 1954, pages 92 and 98.)

The urban environment in underdeveloped countries has therefore the effect of increasing greatly the anxieties and uncertainties of the recent migrant, to make him look for security in familiar surroundings, and to seek out associations in which familiar patterns of social structure, authority, and responsibility prevail. This creates a sentiment of strong ambivalence towards the city, even on the part of those who have come to the city because they were attracted by its glamor and of those who have no place else to go, for whatever reason they came. It further explains why the pushes in order to impel people

to migrate to the cities must be so strong, and why, in spite of apparently appalling conditions in some of the overcrowded rural areas of India, Java, and other parts of the underdeveloped countries, people continue to remain in their villages.

V

And yet we find cityward migrations in underdeveloped countries which are larger than is warranted by the newly created economic opportunities in the cities. Here is another difference between the cities of underdeveloped countries and those of the advanced countries. The rapid growth of the industrial cities of Western countries occurred simultaneously with the rapid growth of industrial investment and hence the movement to the cities was in large part a response to the opening up of new employment opportunities there. To be sure, many migrants had only very dim expectations as to what they would find in the city, but wave after wave of migrants found even fairly optimistic expectations confirmed. Sometimes they had to suffer hardships and deprivation for a period; sometimes they flourished as soon as they arrived. But during the entire growth process of the cities in advanced countries, the expectations of the migrants to find employment and improve their economic position were confirmed in the long run.

The pattern of cityward migration in the underdeveloped countries is different. Some migrants are attracted by the glamor of the city and some by expectations of economic improvement. But most persons who come to the city are pushed out from where they have lived before by events beyond their control. In some cases it may be the rigors of famine and other material hardships which drive people out, in other instances it may be civil war and banditry, but in most cases the forces which succeed in pushing people into the cities are persistent and strong.[10]

The most rapid growth of cities in underdeveloped countries took place in the last few years. Accurate figures are not available for all countries, but we have fairly good estimates for the growth of cities in some countries. Some very interesting estimates of urban growth in Indonesia have been published by W. L. Utermark. He presents a table in which he lists fourteen of the largest Indonesian cities, dividing them into two groups. One group is composed of cities which grew

[10] See Wilbert E. Moore, *Industrialization and Labor* (Ithaca, 1951), especially pp. 48-70 and 94-96. On cityward migrations due to famine, see Owen Lattimore, "The Mainsprings of Asiatic Migration" in Isaiah Bowman (ed.), *Limits of Land Settlement* (New York, 1937), p. 133, and Walter H. Mallory, "The Northward Migration of the Chinese," *Foreign Affairs,* October, 1928, pp. 80-81 (migration of Chinese to Manchuria out of famine-stricken areas in Shantung and Hopei). The main instances of cityward migration as a consequence of civil war and banditry occurred in recent years in Indonesia, Burma, Malaya, and the Philippines.

primarily because of cityward migration from their immediate hinterland, apparently motivated largely by economic opportunities in the city. The other group is made up of cities which grew primarily because people from all over the country hoped to find in the city shelter from insecurity, political advancement, or other opportunities associated with the rapid social and political change of the times. The first group embraces seven cities which in 1930 had a combined population of 536 million and in 1950-51 of 977 million. The second group also embraces seven cities which were inhabited by 1,386 million people in 1930 and by 4,329 million in 1950-51. The rate of growth in the first group was 82 per cent and in the second 212 per cent.[11] This shows that not only are the largest cities growing faster than the smaller ones, but also that cityward movement was considerably more important for noneconomic reasons than for economic ones.

It is not difficult to assess the consequences of this form of development. In the first place, it adds to the insecurity and stress which the migrant to the city experiences. Not only is he torn from his accustomed environment, but he finds that his very existence is put in question in the city. He literally lives from hand to mouth; he is available for any job to be had (including hiring himself out for political demonstrations or rioting);[12] he becomes demoralized and an easy prey for radical agitators of all hues; he lives in unspeakably rotten slums, much worse than those of Manchester in early Victorian times, and scarcely equaled by the *bidonvilles* of North Africa and Spain. A large proportion of the poor people in many underdeveloped towns are not an "industrial reserve army," but a demoralized, unhealthy, pitiful *lumpenproletariat*. Even if a sudden spurt of industrial investment were to take place in these cities, it would be difficult to transform these people into disciplined, effective factory workers.

Another aspect of this recent in-migration is the very high sex ratio in many cities of underdeveloped countries. This phenomenon is not unknown in advanced countries. Among the immigrants from Europe to the New World, men were in the majority, and if we omit persons under eighteen years of age, the proportion of male immigrants increases. Most of these immigrants went to cities, and hence one many say that here was a predominantly male cityward migration. In the underdeveloped countries, also, men predominate so strongly among the migrants that the sex ratios in cities are extremely uneven. For example,

[11] W. L. Utermark, "Aspect économique de l'attraction exercée par les centres urbains et industriels en Indonésie," in *L'attraction exercée par les centres urbains dans les pays en voie d'industrialisation* (Brussels: Institut International des Civilizations Différentes, 1952), pp. 226-234, especially p. 232.

[12] I am told by an American official, resident in Iran, that participation in political rioting—one day for and the next against Mossadegh—was one of the more attractive forms of making a livelihood for a portion of Tehran's *lumpenproletariat*.

in four of the eight largest Indian cities the preponderance of males is very strong. In Calcutta there are 602, in Bombay 569, in Ahmedabad 764, and in Kanpur 699 women per 1,000 men. Similarly, in Africa the male urban population is much larger than the female. In the Belgian Congo, for example, there are 696 women per 1,000 men.[18] In many of the mining camps of the Copper Belt in Rhodesia or the Rand in the South African Union the imbalance is even stronger.

The consequences of these facts are not difficult to assess either. The great preponderance of males means that stable families are rarer in cities than in the country. The men who come to the city are single or leave their wives behind. In the former case they may regard their stay in the city as temporary, since they often come in the hope to make enough money to go back and get married. In the latter case they do not break their close tie with their native village; they are not city dwellers but temporary residents. This situation adds to the instability of the city population in underdeveloped countries. It also adds to the stress experienced by the new immigrants and is one of the chief causes for the prostitution, gambling, racing, dope dealing, and other forms of social disorganization and crime which Motwani notes with so much displeasure.

All these factors conspire to make the large cities in underdeveloped countries highly unsuitable places for the development of new forms of social cohesion and solidarity. Although whatever change in the culture and social values occurred in Asia and Africa did primarily take root in the cities and then emanated from them, the changes that have actually been achieved have been slow and halting, often impeded by the lack of unity, instability, and heterogeneity of the city population. If progress towards universalistic, achievement-oriented social values has been difficult in the cities of Asia and Africa, it is not due to the stubbornness of the people or their "superstitious" adherence to old ways of life, but rather to the very unfavorable conditions under which they have been brought to the city and under which they continue to exist.

VI

It is in the light of this contrasting impact which cities have exercised in advanced countries and now exercise in underdeveloped countries that we have to appraise the industrialization of less advanced countries. The analysis of this aspect of economic development can be short because there exists already a considerable literature

[18] The figures for India are for 1951. Cf. India, Census Commission, *Census of India, 1951* (Delhi, 1953), Vol. I, p. 56. The figures for the Belgian Congo are for 1940. Cf A. J. Moeller de Laddersous, "Attraction exercée par les centres urbains et industriels dans le Congo Belge" (Institut International des Civilizations Différentes), *op. cit.*, p. 192.

on this subject.[14] In principle, we may distinguish three types of impact exercised on a nonindustrial labor force by the introduction of mechanized industry. The first is the need for adjustment to the new environment, and it is particularly in this area that the new urban agglomerations are important factors in the formation of an industrial labor force in underdeveloped countries. The second impact is that of a new technology: the replacement of handicraft work by machine work, the acquisition of new skills, and the co-ordination of the tempo and rhythm of work with the machine rather than the freer and less rigorously structured pace of the artisan. The third impact is the imposition of new social relations appropriate to modern forms of industrial organization: new hierarchies, new social groups, new patterns of authority develop which are strange and often contrary to those to which the new recruits of industry are accustomed. The workers find themselves in situations which in terms of their old culture either have no analogue or which are flatly opposed to the old culture. The high-caste Indian, working side by side in a factory with a low-caste Indian; the mixture of different racial or ethnic groups in a factory who previously held strictly aloof from one another; the congregation of people who previously had known co-operation only on the basis of kinship ties, in a labor union or a sectional work crew in a factory—all are cases in point.

As concerns the impact of the urban environment, little needs to be added to what has been said before. The city in an underdeveloped country is an inhospitable environment for many actual or potential laborers. Reference is made not so much to slum conditions and bad housing, although these have detrimental effects on the morale of an industrial labor force. Nevertheless, in many underdeveloped countries actual health, sanitary, and housing standards are no worse, and often better, than in the rural areas whence the workers come. To be sure, conditions are often worse than they were in nineteenth-century Europe, but compared with what the cityward migrant in many underdeveloped countries left behind, his standard of real welfare suffers hardly any diminution. The inhospitality of the urban environment expresses itself rather by the serious psychological strains it exerts on the worker. Employment is uncertain and wages too low to permit savings for a rainy day. Families are torn asunder; the comforting security of a known and accustomed environment is lost. The number of face-to-

[14] In adition to Wilbert E. Moore's book, mentioned earlier (in note 10) there exists a considerable literature on this topic sponsored by UNESCO, ILO, and various national governments. A good bibliography is contained in Wilbert E. Moore, *op. cit.*, pp. 365-398. Other writings are listed in *Current Sociology: International Bibliography of Sociology*, Vol. I and ff.; and Daniel Craemer, *Bibliography on Income and Wealth*, Vol. II (Cambridge, 1953), especially under the headings "Estimates of Labour Force by Geographic Areas" and "International Comparisons of Labour Force Estimates."

face relationships with persons whom one does not know is increased; the loneliness of the individual becomes, in some cases, almost absolute. These conditions impair morale, discipline, and steadfast devotion to a given task. It is not the noise or the soot in the city which corrodes the nerve of the worker, as Motwani has it, but rather the "absence of neighborhood"—the anonymity and impersonality of life in a big city. These factors go far to explain the high absentee rate, the high rate of turnover, and the low standard of performance of many industrial workers in underdeveloped countries.

The impact of the new technology pales in importance besides this impact of the urban environment. New skills can be learned and have been learned with surprising speed by many peoples. It has been pointed out again and again by anthropologists that the technical manipulations involved in handling complex machines have been learned with relative facility by peoples in underdeveloped countries who had no previous knowledge of these machines and whose general standards of literacy and education left much to be desired. No less an authority than the late Ralph Linton wrote: "I would back certain Polynesian and Swahili mechanics of my experience against nine-tenths of American garagemen for ingenuity and mechanical know-how."[15] The retarding factor is not the incapacity or lack of interest on the part of workers in underdeveloped countries to acquire the requisite skills but rather the inadequate provision for training, the great shortage of educational facilities, and the impediments, in many instances, to advancement which deprive workers of incentives to improve their performance. The "demonstration effect" described by Ragnar Nurkse with reference to changes in consumption patterns of the peoples in underdeveloped countries exercises an influence here also. (*Problems of Capital Formation in Underdeveloped Countries* [New York, 1953], pages 64-65.) Imitation of Western methods and the use of Western machines are recognized as means to increased output and ultimately better living standards. What is absent is not the willingness or human ability to use these machines and methods, but the social institutions which permit their use to these ends.

This leads us to the knottiest and most difficult problem in the industrialization process in underdeveloped countries: the impact of the new forms of social structure and the requirements of new types of social behavior appropriate to large-scale production in the factory. The restructuring of social relations occurs as a result of the mobilization of the labor force implying the imposition of cannons of employ-

[15] "Cultural and Personality Factors Affecting Economic Growth," in Bert F Hoselitz (ed.), *The Progress of Underdeveloped Areas* (Chicago, 1952), p. 78. Linton presents an exhaustive discussion of this point, giving other examples on pp. 77-79.

ment prevailing in the industrial communities of Europe and America. It is hardly necessary to point to the striking differences between the economy in the West and that of most other societies. In the West it is based upon individual effort, whereas most of the other peoples are communally-oriented. Hence in the West the worker acts as an individual. In the economies of most underdeveloped societies, on the other hand, the individual acts usually as a member of a group based on kinship or residence or both. His responsibilities are considered not merely those he individually undertakes, but also those of the other members of the group to which he pertains. Similarly any compensation he may get for his effort is regarded by him not merely as a reward to be employed for his individual purposes but to be shared with the other members of the collectivity of which he forms a part. In many societies there are still recognized traditional arrangements for the control of money income which secure to the older members of the community the major handling of what money income is secured. Laborers must share their income with chiefs, parents, fathers-in-law, or other relatives and persons of respect.[16] In addition to this, the ranking of persons in terms of traditional status relations may differ considerably from that established in a factory work situation. Older men or chiefs or other persons with high traditional status may be subordinate in the factory to younger men, and this subordination may express itself not merely in a lower wage but in actual positions of inferiority in the factory hierarchy or a work crew. The disruptive effects not only on traditional social structures but also on the psychological security of the persons involved are obvious if a man with high traditional status must obey orders of someone who in the traditional ranking is far below him simply because the new distribution and valuation of skills makes this new relation mandatory.

I do not wish to suggest that these changes should be prevented in order to maintain an old cultural tradition or even to preserve certain traditional social structures from disruption or disorganization. I am merely pointing to these changes which, in the light of productive efficiency, may be necessary in the new work situation, in order to explain why the new social relations established in the factory are often contradictory to the traditional and accepted views of a man of himself and his relation to his fellowmen. It is also important to state that, other things being equal, the farther removed the factory is from the locus in which traditional social relations exist, the easier will it be accepted and the fewer psychological or cultural impediments will

[16] A number of such instances are reported by Raymond Firth, "Money, Work, and Social Change in Indo-Pacific Economic Systems," *International Social Science Bulletin*, 1954, pp. 406-407.

stand in its way. A factory located in a village in which the old culture is still strong and vigorous is likely to create more conflict than one located in a far-away city. The more homogeneous, moreover, the labor force in a given factory the more likely will be its resistance against changes in the accustomed patterns of authority and responsibility. (An instance of this is reported by John Useem, "South Sea Island Strike" in Edward H. Spicer [ed.], *Human Problems and Technological* Change [New York, 1952], page 149-164.)

VII

We are now in a position to draw together the various strands of this analysis. The impact of the modern factory is exerted along technological and social-structural lines. The former create relatively few difficulties, but the latter may be a cause of serious maladjustments and resistances reflected in the over-all low productivity of the labor force. These impediments to effective control over the labor force result from the contradictions—which are not necessarily present, but do in actual fact occur often—between the traditional structure of the social status system and the new social relations created by the work situation in the factory. The city, on the other hand, has the definite tendency to break down the old cultural traditions and to weaken the influence of traditional status considerations and interpretations of the worker's place in the social hierarchy. Though residence in a city may create anxieties and stress often bordering on *anomie,* this very same process may produce the result of creating in the co-operation with other workers in the factory an environment in which the new social relations established there may come to be regarded rather as a positive integrating than a disorganizing factor. A recent migrant who feels lonely in the city may welcome the relative security resulting from his being placed in close daily contact with individuals whom he gets to know and with some whom he may become friendly. To be sure, one should not exaggerate the loneliness experienced by many recent migrants to the cities of underdeveloped countries. They usually find some person to whom they are related by kinship ties or ties of previous residence. And if this fails, they get in contact with persons who speak the same dialect and come from the same general portion of the country as they themselves. This enables them to maintain at least a semblance of group relations along traditional patterns. But the closer these group relations are to the traditional pattern and the more intimate the cohesion of this traditional collectivity, the greater will be the difference between the interpersonal relationships in this group and the pattern of social relations in the factory.

This then is the price paid by peasants who come to the city where

they are forced to become industrial workers. The transformation of a predominantly rural society, based on the relatively complete self-sufficiency of a village or a group of villages, into an urban society, based on the interdependence of various portions of a country, is necessarily associated with features of social disorganization. On the sociopolitical level they appear in the form of increased crime rates, imbalanced sex ratios, political extremism, and various other kinds of social maladjustment which usually demand some centrally implemented policy in order to be remedied. On the level of the individuals most concerned, i.e., the nascent industrial workers, this process manifests itself in the increase of stress either due to the new urban environment or the new social relations prevailing in large-scale factory production. In many cases these two sources of stress pull in the opposite direction. If the migrant to the city finds an already established community there in which accustomed intergroup relations prevail, the impact of the new social relations in the factory tends to produce the stress. If he does not find a group in the city resembling those of his home, the loneliness and anxiety which he experiences are the chief causes of stress, and the entry into a new system of social relations in the factory, in a work crew, or a trade-union may be a factor of mitigating this stress.

The persons who in the last few years have swelled the cities of underdeveloped countries do, in a sense, play the role of pioneers. The gap in culture, form of economic activity, and patterns of social relationships which they had to bridge will become narrower for those who follow. But the magnitude of the task and its ultimate importance for the welfare of the total population of underdeveloped countries appear to make these sacrifices justified. It is the toll which a rural peasant society has to pay to become urbanized and industrialized.

DISCUSSION

GEORGE B. BALDWIN: The title of our session can be interpreted in two different ways and this our speakers have done. Professor Moore has selected one of these phenomena—industrialization—and has addressed himself to it alone. Professor Hoselitz, on the other hand, has analyzed the relationship between urbanization and industrialization.

Moore is concerned with the development of a low-order theory of human motivation that will enable us to predict how preindustrial populations will behave in a variety of ways that are significant in determining the progress of their transition to an industrial society. Guarding his rear with a suitable set of qualifications, Moore takes to task both the economists, whose oversimplified assumptions about a universal human desire to maximize limitless economic satisfactions lead them to an unwarranted optimism about the potential rate of industrialization, and the anthropologists and sociologists, whose humility before the facts of psychological complexity and cultural relativity lead them to underestimate the possibilities for development and to be anxious about its individual and social consequences.

After contrasting the motivational assumptions underlying economic theory on the one hand and anthropology and sociology on the other, Moore reviews the empirical evidence concerning experience with the recruitment and utilization of labor in undeveloped areas. In the light of this evidence, he attempts to identify the elements out of which a low-order theory (presumably, at last, an interdisciplinary theory) can be built that will allow us to predict experience with labor recruitment and labor utilization. For a spokesman from a pessimistic breed, Moore offers us a remarkably optimistic theory: although human wants in tradition-bound, preindustrial societies are often limited in the early stages, the evidence suggests that we can expect both wants and, consequently, the supply of labor to expand with the spread of knowledge, education, and the growth of new values. This emphasis on changes in human motivations and aspirations over time—changes which can be accelerated by appropriate policies and practices—certainly makes sense in terms of my own limited research on the growth of industry in South India. Moore concludes with a general plea for the cultivation of a "sense of social participation" among workers in new industrial societies as partial compensation for their uprooting from their traditional mode of life.

Professor Hoselitz is less concerned with model building. He pursues the utilitarian objective of trying to "isolate the impact of industrialization from that of urbanization" so that economic planning can proceed on a more informed basis. We are cautioned that there is no necessary connection between urbanization and industrialization, but Hoselitz accepts the view that economic development will be well served where both phenomena occur together. He then analyzes certain key characteristics of the industrial cities of the West and compares "industrial" and "central" cities in both underdeveloped and

advanced countries. Hoselitz places much emphasis on the historical role of urbanization in confirming and accelerating the spread of those rationalistic, universalistic, achievement-oriented habits of thought on which industrialization depends. Equally important, historically, was the growth of what Hoselitz calls "city-consciousness" (closely akin, I take it, to civic pride) in helping the new urban populations of the West accept their transfer from a rural to an urban environment. This "city-consciousness" or "sense of community" seems to be almost wholly lacking in the mushrooming urban centers of Africa, Southeast Asia, and "perhaps" in South America. The result in these cities is the development of discontented, maladjusted populations that have little unity and that do not transfer their psychological roots to their new environment. As a consequence, these cities are not favorable environments for the growth of those attitudes that seem essential to industrialization.

Hoselitz concludes by summarizing industrialization's threefold impact on a preindustrial labor force:

1. People are forced to adjust to a new environment—a city. This necessarily involves social disorganization which manifests itself, at the social level, in higher rates of crime, unbalanced sex ratios, political extremism, and the like. These maladjustments require "some centrally implemented policy" if they are to be overcome.
2. People must adjust to a new technology. This is the least difficult of the three adjustments and requires mainly an increase in the number of vocational training facilities.
3. People must submit to new social relationships, particularly those required by factory organization. Hoselitz finds this adjustment the most difficult in the whole process of industrialization.

So much for the main papers. There are just three comments I want to make about them.

First, what of Professor Moore's attempt to construct a new low-order interdisciplinary theory of worker behavior? To my mind, this does not come off very satisfactorily. Indeed I doubt that this is the direction in which those of us concerned with economic development ought to push. I say this because of what I feel to be the inherent difficulty of the task: as soon as we try to build a model that will embrace the psychological complexities and cultural differences to which Moore pointed, our model becomes so abstract and qualified that it loses all usefulness as a map to the real world. At the end of his paper Moore himself seems to abandon his own proposal for something strangely similar to the economist's (or at least the labor economist's) traditional model of the labor market. However, Moore rightly points out that it may take considerably more time to realize, in an underdeveloped economy, the behavior responses that the economist's model predicts. In short, if we could agree on how long the "long run" is, maybe we would find the economist's model less misleading than Moore initially suggested. In model building, we can substitute time for noneconomic disciplines: the longer the time period, the more narrowly "economic" we can afford to be in our theory.

After all, the theoretical economist's model of human behavior is not very

much farther off the mark when applied to the preindustrial labor market of underdeveloped areas than labor economists have found it when analyzing behavior in the labor markets of Pittsburgh or Detroit. That model has not been found useless, but it has stood in need of adjustment and caution in its use. A similar adaptation seems in order when analyzing the problems of backward areas. Certainly my own attempt to understand Bangalore, South India, as a labor market was greatly helped by traditional economic theory and by familiarity with Western personnel and industrial relations practices. I mention this because it was the similarities, not the dissimilarities, that leapt to mind in comparing these Indian and American labor markets.

Having made my defense of economics, let me hasten to add that the study of economic development does require that economists pay much more explicit attention to the traditional parameters of their discipline. This will inevitably bring them into closer touch with anthropology and sociology, even with anthropologists and sociologists.

My second comment is suggested mainly by Professor Hoselitz' paper. It is the very pedestrian point that we badly need a lot more empirical research before we begin taking our theoretical generalizations very seriously. Hoselitz' paper struck me as first-rate example of the way in which an imaginative and widely-read scholar can stimulate new insights and suggest specific topics for research by giving us some bold generalizations. But he makes many specific statements to which I would take exception. We need to test such generalizations with intensive case studies of industrial growth and urbanization in a number of countries. In doing this, we shall need to break up the phenomenon of "industrialization of the labor force" into many specific problems: labor mobility, vocational training, union organization and collective bargaining, recruiting methods, wage structures and methods of payment, absenteeism, turnover, labor productivity, company welfare policies, promotion arrangements, and so on. Similarly, specific studies on aspects of urbanization are equally required. What evidence is there, for example, that the city planning movement, which is surprisingly strong in some Indian cities, may be able to affect the shape of industrialization in such a way that the less attractive features of industrial urbanization can be avoided and that a sense of community can be developed?

Finally, my third and most important comment is to point out what I felt to be an important omission from both papers; neither lays any stress at all on what I feel may be the most important factor in conducting a tolerable transition from a preindustrial to an industrial society. This factor consists of the attitudes, policies, and skills of employers. I want to suggest that perhaps we ought to hope for and encourage the spread of a specific employer policy that nearly all of us are glad is dead and buried in this country; namely, "welfare capitalism" based on an attitude of paternalism. This implies company housing, company schools, company doctors, company stores and banks (preferably co-ops, as is common in India)—indeed, whole company towns. I would even go so far as to suggest that company unions ought to be formed where no other unions exist.

The spread of such paternalistic practices will bring abuses, of course; but

more often than not the alternative in many underdeveloped countries will be no—or intolerably bad—housing, no schools, no medical facilities, the abuses of the independent moneylender, and no unions. The absence of alternative social arrangements to provide such foundations for industrial communities quickly strikes one even in such a relatively advanced country as India. There would be great difficulties in execution, in potential and real abuses, in stimulating employer concern for such behavior, and possibly in straining scarce capital resources. But I wonder if welfare capitalism does not provide the best hope of minimizing the social disruption and individual anxieties that accompany the early stages of industrialization?

WILLIAM H. KNOWLES: I should like to raise one point in Wilbert Moore's paper, but one that is relevant to Bert Hoselitz' paper as well. It seems to me that Professor Moore too casually sets up a problem of which comes first: a value system which makes a dynamic market economy possible; or a market economy which brings about a compatible value system. When I observed in the West Indies both that natural resources were not being fully exploited and that profit-making opportunities were not being taken advantage of, I was initially impressed with the argument of social anthropologists that the value system obstructed economic development. Further study, however, has caused me to reverse my stand and to believe that social anthropologists have overstressed resistance to economic progress. Instead, I would now argue that the act of setting into motion of technological change will necessarily bring about rapid cultural change.

First, the concept of society in equilibrium is as unrealistic as is the notion of an economy in equilibrium, and both economists and anthropologists are sometimes guilty of confusing their theoretical models with the real world. Change has been taking place in the cultures of underdeveloped areas ever since the arrival of the first explorer, trader, and missionary. The fact is that the societies of the underdeveloped areas are presently in an advanced stage of disintegration and this instability is the very reason why we are concerned with the economic development of such underdeveloped areas. (Dewight Cooke, *There Is No Asia* [Doubleday, 1945], pages 261-262.) The fact that these societies do not seem to be resistant to change by communist infiltration makes the real issue the question of what kind of value system will replace the old.

Second, I believe that the social anthropologists are in error in their observation that what the economist calls rational economic behavior is merely a value judgment and varies from one society to another. It is true that the West Indian peasant behaves rationally when he plants the smallest possible garden close to his door because he knows his neighbors will steal his produce. It is also rational for him to steal from his neighbor's garden. But the peasant community collectively is behaving irrationally when it suffers hunger because of such a "value system." A more likely anthropological term for such irrational economic behavior was used by Madeleine Kerr when she described the behavior of Jamaican peasant communities as pathological. (Madeleine

Kerr, *Personality and Conflict in Jamaica* [Liverpool: University of Liverpool Press, 1952].)

Third, I believe that the problem, in the West Indies at least, is more nearly one of getting a stalled or stagnate economy moving in the right direction than it is one of value systems. Professor Moore pointed out that a vicious circle often develops when employers pay low wages because productivity of labor is so low, and when employees respond by doing as little work as possible because wages are low. Both employers and employees may be considered to be acting rationally, but the resulting low standard of living leads to unstable political conditions of revolutionary proportions. Such a vicious circle is as much a problem in economics as it is one of value systems. From my research in the British West Indies, I would like to list a few specific economic problems to explain attitudes towards work and the resulting low level of economic activity.

Lack of Effective Merchandising. Businessmen do not attempt to create new consumer desires because workers lack purchasing power, and similarly labor is not motivated to work because they do not have unfilled wants. To explain this the social anthropologist concludes that man's wants are not insatiable as assumed by economists. I say that American merchandising methods can make man's wants insatiable even as they are in the United States. An American timber operator in British Honduras explained this to me by saying that industrial discipline is lacking there because the workers were not "hooked." By contrast, workers in Panama have become efficient because they are now hooked, he said. They were caught, he explained, because their wives learned to demand nylon panties and workers had to earn the money to buy such goods. On the other hand, he had just returned from his first visit in twenty years to his home town of Los Angeles and he was shocked by how hard people worked and how much they wanted. They were hooked too completely, he had decided, by American merchandising methods.

Lack of Effective Management. Labor cannot be highly motivated where it is not trained, where supervision is poor, where work standards are slack, and where workers are treated as inferior beings. Low productivity proves to management that workers are indeed inferior and it is therefore futile to attempt modern personnel practices. This vicious circle may be rational or may be part of the culture's value system, but the report of many West Indian workers to the effect that when the boss treated them as though they were dull they played dumb, makes more sense to me.

End of Racial Discrimination. When opportunity for advancement is denied on racial grounds and when wage differentials are based upon color, labor not only fails to be motivated but also indulges in mild forms of sabotage. In this case, however, it is the irrational value system of white Europeans and North Americans that causes the people of underdeveloped areas to resist industrialization and urbanization. There is no color bar in peasant villages and resistance to industrialization may be more of a resistance to undignified treatment common to urban areas than resistance to work or lack of interest in a higher standard of living.

Lack of Capital Equipment. Labor in the West Indies associates work with slavery when it is menial work done with cutlass and hoe. A study by Simon Rottenberg of labor attitudes in Antigua showed that there could be general underemployment while at the same time there was a labor shortage in the cane fields. (Simon Rottenberg and Nora Siffleet, *Unemployment in Antigua* [Labor Relations Institute, University of Puerto Rico, 1952].) Laborers are reluctant to demean themselves by wielding a hoe when they would welcome the chance to drive a tractor. Labor is motivated to work where capital equipment gives relief from backbreaking physical labor and will accept the improved dignity and status that machine operated jobs give over that of field hands.

Substantial Wage Increases for Increased Productivity. It is true that small wage increases tend to reduce the supply of labor through greater absenteeism, but sizable wage increases serve as an inducement to break with the past and assume lower middle-class virtues of hard work, thrift, sobriety, and ambition—exposing the hook to the bait. Professor Hoselitz' description of city dwellers of Asia who failed to acquire the urban value system known in Europe and North American cities was also describing workers whose wages are very low and who are chronically underemployed. Labor prefers work to the leisure of tribal or village life if the compensation is large enough to permit them to assume the urban value system.

Lack of Full Employment. The neoclassical model outlined by Professor Moore also assumes full employment, and behavior patterns are different where there is chronic unemployment. Lack of ambition is frequently lack of job opportunities, and laziness is often an unofficial share-the-work program. My colleague, Professor Anthony Koo, reports that women employees of a new textile mill in a Chinese village quickly broke from parental authority, refused to marry the husbands that had been chosen for them, and demanded that the village stores carry cosmetics and Western clothing. As we have learned in the United States in the transition from depression to prosperity, there is nothing like a job and purchasing power to change a person's values.

Poor Health and Diet. Taking issue with Professor Hoselitz, I believe that an industrial reserve army does exist in underdeveloped areas if workers are made healthy and given a blanced diet. Professor Reynolds' example of the happy Bantu whose value system caused him to prefer leisure to work is probably idyllically descriptive of the fact that the Bantu is suffering from malaria, tape worms, and malnutrition. Thus the Bantu value system is probably based upon physical inability to work. The Republic Steel Corporation was able to exploit the rich iron ore deposits of Liberia, where other companies had failed, by first restoring the native workers to health and then giving the proper food and housing.

Stated in these terms, the worker's attitude toward industrialization and urbanization is not so much a problem of value systems as one of vicious circles which lead to irrational behavior for society as a whole and, in turn, to revolutionary upheavals. In his presidential address before the Industrial Relations Research Association, Clark Kerr stated, correctly I think, that the revolution of the peoples of the world was in favor of industrialization and this creates problems in the rearrangement of social structures. We have the

know-how to bring about the industrialization and we have the merchandising and personnel techniques to overcome the economic stalemates listed above. Our central problem is to keep the manpower and resources of underdeveloped areas from succumbing to communism. The creation of jobs, purchasing power, and a desire for a higher standard of living can be our chief weapons in the fight. Let us proceed with plans for industrialization and the value systems will take care of themselves.

SIMON ROTTENBERG: Messrs. Hoselitz and Moore have written perceptive papers which raise meaningful questions and deal with them meaningfully. In this discussion, I shall not speak of the majority parts with which I agree, but only of the minority parts with which I take issue.

As Mr. Hoselitz correctly says, growth can, and has, occurred in other ways than through industrialization. I think it is true that economies have grown almost everywhere in the world in the last half century. Almost everywhere, income per head of population is larger than it was fifty years ago, and this is true despite the increase in numbers that has also occurred almost everywhere. But industrialization—if by this we mean manufacturing industry—has not occurred everywhere. If people are, on an average, better off now in the Rhodesias, it is in large part because of copper and tobacco; in the Gold Coast, coca; in Assam, tea; in Malaya, rubber and tin; in Ecuador, bananas; in Venezuela, oil; in Colombia, coffee; in Cuba, sugar; in Iowa, corn and hogs; and in Florida, tourism and citrus fruits.

The number of cases in which per capita income increments have been achieved through agriculture, mining, and other nonmanufacturing forms of economic activity is very large.

It is significant, also, that that within the last several decades, in the United States and in Europe, some cities have become "too big." As diseconomies of scale were encountered, entrepreneurs making locational decisions have tended to choose metropolitan area fringes in preference to their centers and, to some extent, small places to large. In the process of locational trial and error, skills have been learned in the administration of decentralized manufacturing that may result in the long run in less congested industrial areas in the poor countries of the world. For both of these reasons, discussion of the functioning of cities in relationship to growth covers less than the whole growth story.

I turn now to the partial case in which growth does occur through the proliferation of factories and where the factories are concentrated in cities.

Mr. Hoselitz says that disproportionate numbers of rural people are attracted to these cities in the non-West, relative to the opportunities that await them there and that these excessive numbers consitute a *lumpenproletariat* but not a reserve (and presumably efficient) industrial army available to new factories.

We need to ask ourselves here: what is meant by opportunity? People move from place to place in any society for many and diverse reasons. The causes of movement are uniform neither among societies nor among individuals within given societies. But it is uniform among both societies and individuals

that movement occurs because people believe they will be better off if they do move. We are compelled to come to this judgment, if we reject the only two alternative propositions: that people make migrational decisions randomly (as by deciding by the turn of a coin) or that they locate where they believe they will be worse off. I think neither of these is a priori tenable, either for Nigeria or for Tennessee. I have said that people's decisions are consistent with the belief that they will be better off. This does not mean that mistakes are not made. They are; but in the end mistakes are found out and new decisions correct errors in old.

This suggests that, all things considered, if there is movement to the cities from rural areas in the non-West, it will not be larger than "warranted." The incidence of unemployment and mortality in the cities may be high and earnings may be low, but either, even at these levels, conditions are better than in the country or else conditions are worse, but people are willing to pay a price in less opportunity for the specialized services and "glamor" which are available in the cities but not in the country.

Multidimensional motivations for cityward migration characterize movement in both the West and non-West. In both, opportunity-for-income differentials and opportunity-for-nonincome differentials play a part. Can we say which of these two has the heavier influence in each, the West and the non-West?

Suppose we accept, as I think we can, the evidence of both papers that non-Western people are psychologically so thoroughly committed to kin, tribe, and village that they trek to the cities only with very great reluctance, while, in the West, the psychological impediments to movement are less formidable. Then we are led to the conclusion that differences in incomes between the cities and the country must be larger in the case of the non-West to induce movement to cities and, from this, to the corollary that numbers moving cityward there are, if anything, less rather than more than warranted, measured by the criteria of growth and efficiency.

Non-Western city slum dwellers may be poor raw material for the factories, but it is for other reasons than that too many have come to the cities. Relative marginal products of labor in city and country are such that the removal of a proportion of present city dwellers to the country can be expected to diminish total output, not increase it.

In one sense, Mr. Hoselitz is right to say that the learning of new skills by primitives and rural people is done quickly. In the absence of contrary evidence, we can, I think, accept the proposition that the genetic capacity to acquire knowledge is about equally distributed among countries. Where the extent of the market makes the division of labor consistent with cost-minimizing choicing within and among firms, the problem of skill learning even diminishes in magnitude, because simple operations are more quickly learned than complex ones and specialization tends to result in simplification.

I have said that the genetic capacity to acquire knowledge seems to be equally distributed in the world. What Simon Kuznets has called the "*social* capacity" to acquire knowledge, however, is unequally distributed. Some societies are characterized by the experimental acceptance of knowledge, by an

empirical outlook, by skepticism, and by change. Others are characterized by sanctification of knowledge, by a mystical outlook, by traditionalism, and by changelessness. In the former, new knowledge is easily accepted when it proves its worth; old knowledge is easily abandoned when it becomes obsolete. In the latter, new knowledge must struggle to make headway against customarily-verified old knowledge. It is this unequal distribution of the social capacity to acquire knowledge which explains, in large part, why new technology diffuses so much more rapidly among Iowans than among the Bantu. In this sense, adjustment to technology does seem to be something of a problem. Adjustment to technology has still another facet which magnifies the problem. If economies are to grow, knowledge must be used as well as acquired; but the use of new knowledge almost always disadvantages those who use old knowledge. The survival of old firms and old jobholders is threatened by new ones. In economies experiencing relatively rapid rates of growth, old techniques are willing, more or less, to let the market decide which shall pre-empt the field. In relatively stagnant economies, on the other hand, old techniques are often buttressed by public policies which protect old jobholders against new entrants, hold an umbrella over inefficiency, and encourage stagnation to feed upon itself.

In the end, looked at from these vantage points, I think that Mr. Hoselitz may have underestimated the seriousness of the problem of technological adjustment in the poor countries. I think, on the other hand, that he may have overestimated, on net balance, the knottiness of the problem created by the persistence of traditional values in the non-Western cities.

The transmutation of behavior governed by some other rule to behavior governed by the rule of efficiency is everywhere a problem when rural or preindustrial people are taken into the factories. But somehow this transmutation occurs. The economic history of the United States is studded with examples of it. It happened first to the rural women of New England who took up work in the early cotton mills and later to successive waves of immigrants from Europe who somehow accommodated imported values and standards to the requirements of competitive survival in a rational economy in which the market disciplined behavior.

In many respects, our cities were also aggregates of distinct clusters, simulating, in some ways, the cities of Africa and the East of which Mr. Hoselitz speaks. In these clusters, the old standards persisted even into the first generation of American-born of immigrant parents, but efficiency on the job seemed to be achieved, nonetheless. To discuss how this accommodation occurred takes us some distance away from economics and I am sure that I am not competent to pursue it. I venture the guess, however, that the immigrants found it possible to live diverse lives by diverse standards, so that in their homes and neighborhoods they obeyed (perhaps incompetent) elders and on their jobs they obeyed (perhaps young) competents.

I do not want to appear to question Mr. Hoselitz' central thesis that our cities are more efficient producers of rational human animals whose choices among alternatives serve the interests of output and individual gain. I should think, however, that patterns of diversity of values similar to ours can be

found to exist in the non-Western cities, too, and that the factories there breed, for themselves, individualization of contract, hierarchy oriented to merit, and the other structures and values of which Mr. Hoselitz speaks which are the conditions of efficiency. This has, at least, been the experience of the poor countries of the Western Hemisphere where the cities and towns have played a primary role in converting indigenous human raw material characterized by very profound adherence to tradition into a stock of human resources appropriate to economic growth.

I think that some of the detail of Mr. Moore's decription of employment choicing in the poor countries is arguable, but I do not propose to argue it here. His description is closely proximate to truth; in some average sense, in the poor countries people are less mobile and less responsive to price incentives than in the rich countries. Strong loyalties to kin and tribe, low aspiration levels, devaluation of new occupations, and so on cause people to be willing to pay a price for traditional structures and systems.

Certain propositions can be appropriately drawn from this evidence. Other things equal, a community which aspires to consume a small volume of goods and services will produce less than one which aspires to consume a larger volume; a community that wants to consume much leisure will produce less than one that wants to consume little leisure; a community of immobile workers will produce less than a community of mobile workers; a community of workers who are indifferent to income will produce less than one of workers who prefer high income to low. But Mr. Moore goes beyond judgments of this kind, to say that choice patterns in the poor countries make economic theory a useless instrument for understanding the processes by which labor is allocated to uses there. This, I think, is wrong and I propose to devote the remainder of my discussion to this question.

The economic theory of the allocation of labor is an enormously versatile analytical tool. Supply and demand schedules are drawn to show functional relationships between quantity and price. But this does not say that theory assumes that quantity is exclusively responsive to price, nor that response is instantaneous, nor that it is uniform among workers, nor that small price changes will necessarily induce change in quantity.

Textbooks in economics carry graphic illustrations of supply curves of various degrees of slope and there is a long history of literature in the journals on kinked curves and their analytical consequences. If the Bantu prefer to stay on their reserves and if they go into the mines only reluctantly, the supply curve of labor to the mines will be more inelastic than if this were not so. Similarly, the preference of Pennsylvania coal miners for staying in depressed towns after coal has been mined out will tilt the curve upwards.

The number of different degrees of slope of supply curves of labor from infinite elasticity to infinite inelasticity is infinite and the number of different complexes of circumstance which can determine any single degree of slope in this set is also infinite.

The analytical apparatus is broad enough to encompass them all. The extreme case of infinite inelasticity of supply is one in which quantity is precisely completely irresponsive to price; theory comprehends even this case.

The individual supply curve of labor does not even have a persistent slope, but turns and twists in its course. The number of different shapes which it may have is also infinite. The diversity of shapes and slopes which theory permits occurs precisely because of differences among men in aspiration levels and in the evaluation of the income and nonincome properties of different occupations.

The labor supply schedule will be more inelastic if a given increase in the supply of labor can occur only with a large increase in marginal cost and if a given increase in the price of labor makes it worth while for only a small number of new workers to make themselves available for work. The components of cost and of the calculus of what is worth while are many and diverse and they include all of the considerations that Mr. Moore has said—incorrectly, I think—are outside the system of the theory of economics.

Economic theorists never said that relative prices alone determine in which employments people will be disposed to place themselves. When price is measured on the *y*-axis in conventional graphic analysis, the other components of jobs are implicit but not omitted; and theory is versatile enough to admit some other variable than price, either alone or in combination with price, to be inserted instead. If such a substitution should give better predictive results than analysis which functionally relates prices and quantity, then the change can and should be made, but the theory will have been substantially unchanged. Much of what Mr. Moore says about the nature of economic theory is, in the light of what I have just said, not correct.

Economic theory does not assume that men make choices among alternatives which are appropriate to the maximization of satisfactions that are "economically defined and measured," if by this is meant income and only income; nor that "human wants are . . . unlimited," if this means that men are not thought to reckon the cost in leisure foregone, effort spent, and other values sacrificed in satisfying wants; nor that " 'human nature' [is] pretty much the same wherever encountered"; nor that "financial incentives are . . . effective in allocating labor," if this means they do so to the exclusion of other incentives or, again, that costs are not reckoned; nor that workers everywhere are equally willing to work; nor that the preference for lower income occupations over higher income occupations is necessarily " 'irrational' or 'nonrational' as judged on economic grounds"; nor that "Western experience can be used as a guide to behavior in Dahomey," if this means that behavior is the same in both.

I do not want to put this case so strongly that the cause of the criticism of theory will be put out of sight. Theory says that people will be distributed among classes of work such that their marginal products are proportional to their prices. If this is not true at some time or place, then it will pay for people to move from one employment to another until it is true. If it is true, the system is in equilibrium and there is no incentive to move.

Now this is a solution to the problem of the allocation of labor which has a quality of elegance. Everyone knows that competitive equilibria are logical ideals; that no system of natural phenomena ever purely achieves these results; and that the pure theory expresses tendencies rather than describing

precisely what transpires in real worlds and real markets, either in the West or in the non-West.

Elegant solutions are derived because it is the nature of theory, in order to simplify analysis, to be highly abstract, to introduce only a few explicit variables, and to hold others constant or to randomize their effects. The usefulness of theory derives from the capacity of abstract, simple, and unrealistic models to yield results which are highly predictive of real phenomenal experience.

Much of the criticism of theory derives from the belief—which I think false—that simple models cannot be used to explain complex phenomena or from the failure to understand that results that are drawn from these models are only tendential.

From all of this, you will have seen that I dissent a little from Mr. Moore's conviction that economic theory has very limited utility for analysis of preindustrial labor markets. I think, on the contrary, that its utility there is about as great as in industrial labor markets. The insights of economists on behavior in different societies are not different from those of the sociologists-anthropologists. The differences are only in the subject matter of the disciplines.

The economist says: my insight is that Peruvian Indian labor is relatively inelastic to price. He proceeds to examine the factor price and resource allocational consequences of inelasticity, but only some of its causes, such as the cost of training, the scarcity or abundance of natural talent, and the restraints on competition. The sociologist-anthropologists says: my insight is that Peruvian Indian labor is relatively inelastic in price. He proceeds to examine other causes of inelasticity and finds them in values held, kinship systems, family structures, and residential patterns. Their studies are not competitive but complementary.

In any case, I think that the price elasticity of labor in the poor countries is not as low as the reiteration of impediments to mobility would make it seem to be. In all of these countries, there is evidence of movement to cities, factories, plantations, and mines, and from other employments where income is lower. This movement is consistent with the expectation of theory that, other things equal, men will prefer higher income opportunity to lower, and its corollary, that because it occurs, average productivity and average output per head will rise.

Just the other day, Robert Oppenheimer, seeing with profound poetic perception what is going on about him, said: "What is new in the world is the massive character of the dissolution and corruption of authority, in belief, in ritual. . . ." For this discussion, this means, it seems to me, that men now, almost everywhere, pursue higher material levels of life more cheaply in psychic costs than they once did.

MODELS OF ECONOMIC GROWTH

CAPITAL INTENSITY AND ECONOMIC GROWTH

By JOHN H. POWER
Stanford University

The purpose of this paper is to explore the theoretical possibility of equilibrating adjustments in the capital coefficient in a growing economy. Professor Fellner has recently called attention to the fact that in projections of economic growth this possibility has been largely ignored, leaving to fiscal policy the whole of the problem of correcting any unbalance. Fellner argues that, in an automatically and fully adjusting economy, "the capital-output ratio would always assume the value corresponding to the postulate that all voluntary savings (plus whatever tax payments there are) must be absorbed by the planned private capital formation (plus whatever government expenditures are made). . . . We all know that the economy is not fully adjusting in this sense. But it should not be assumed that the economy is fully nonadjusting in the same sense."[1]

The first section of this paper sets the problem in terms of a crude growth model. It should be emphasized at the outset that this model is not offered as a general model of economic growth, but as a device for concentrating on particular questions in growth theory. In the second section we turn to a reconsideration of the theory of capital intensity. The results therein obtained are applied in the final section to the issue raised by Fellner. Some concluding remarks follow the final section. The analysis throughout pertains to a period longer than a business cycle; and for simplicity we consider a closed, private economy with only two factors: labor and capital.

I

The problem of stable growth is ordinarily posed as that of maintaining balance in the rates of growth of a few aggregates: total demand, the capital stock, and the labor force. The condition for stable growth in this somewhat restricted sense can be stated as follows: potential total output given by the existing labor force and capital stock must be matched at all times by the total demand for output given by

[1] William Fellner, "Long-Term Tendencies in Private Capital Formation," in *Long-Range Economic Projection*, Studies in Income and Wealth, Vol 16, Conference on Research in Income and Wealth, a report of the National Bureau of Economic Research (Princeton University Press, 1954), pp. 301-302

the saving function and capital formation, where the latter is just sufficient to equip increments to the labor force in the optimum ratio.

This is shown graphically in Figure 1.[2] *L* and *dL* represent, respectively, the labor force and its annual increment. *S*, *I*, and *Y* are net saving, net capital formation, and total net output, all per annum. The slope
FIGURE 1

of the *g* function is simply the percentage growth of the labor force. The slope of the *c* function is the capital coefficient (here stated as a ratio of capital to labor instead of, as is usual, of capital to output). It is assumed that investment decisions are undertaken automatically to equip increments to the labor force in the optimum (most profitable) ratio of capital to labor as given by interest rates, wage rates, and the prices of current output. The stock of knowledge will initially be held constant, and the possibility that a changing pattern of demand will alter the optimum ratio of capital to labor for the economy as a whole will be ignored.

The *s* function is the saving-income relationship and, together with capital formation, gives the total demand for net output, Y_d. Finally, the labor productivity function, *p*, gives the relationship between the labor force and the total supply of net output, Y_s, for a given (optimum) capital stock. There is a balanced relationship among the aggregates if Y_d and Y_s meet on the *Y* axis (alternatively, if investment and saving meet on the *S*, *I* axis).

If, however, the rate of growth of the labor force were higher, Y_d would exceed Y_s, resulting in a chronic tendency toward inflation. At the same time there would be rising unemployment (though it might

[2] This diagrammatic representation was suggested to me by Paul J. Wells, of Stanford University.

be "disguised") since a part of each increment to the labor force would fail to be supplied with capital equipment (assuming that forced saving does not equal the total gap between Y_d and Y_s; i.e., that real investment suffers as well as real consumption as a result of the inadequacy of total output).

When, on the other hand, the rate of growth of the labor force is insufficient to require capital formation equal to the flow of saving, Y_d falls short of Y_s and part of the existing labor force is unemployed. If no adjustment occurs in the functions, unemployment grows over time. In the first case, we have chronic inflation with growing unemployment; in the second, we have chronic depression with growing unemployment.

In a general theory of economic growth, we could not simply take it for granted that the atomistic decisions of individual entrepreneurs would provide all increments to the labor force with equipment in the optimum ratio. Indeed, this might constitute a major part of the adjustment problem in an automatically adjusting economy. But an adjustment in the capital coefficient is not the appropriate remedy when unbalanced growth results from a failure of capital widening to proceed at the rate warranted by the growth of the labor force. If, for example, in an otherwise balanced situation, the actual rate of widening fell short of the warranted rate, resulting in a chronic deficiency of demand, a rise in the capital-labor ratio would reduce the deficiency of demand without eliminating growing unemployment. The problem is not solved, that is, by adopting production techniques which raise the ratio at which only a part of each increment to the labor force is being equipped with capital. Thus, the question of appropriate adjustments in the capital coefficient arises only when the adjustment of capital widening to the warranted rate has been accomplished (by automatic forces or government policies). But the question does arise in this case, for the warranted rate may exceed or fall short of saving.

Again, in order to concentrate on adjustments in the capital coefficient, we rule out Malthusian adjustments of population growth to wage changes and classical adjustments of saving to changes in interest rates. The rate of growth of population and thriftiness are the independent variables in the model.

Thus the issue comes down to this: will there occur automatically equilibrating adjustments in the capital coefficient when the growth of the labor force is not consistent with the flow of saving? A certain growth in the labor force will require a certain increase in equipment at the optimum ratio if the new labor is to be employed. This net investment may or may not equal the saving out of the income corresponding to the output produced by the existing (fully employed)

labor force and capital stock. If investment exceeds saving, a fall in the marginal capital-labor ratio would be equilibrating in the sense that it would reduce the excess investment. In the opposite case a rise in the ratio would be equilibrating.

There is a further complication, however. The relation between the labor force and potential output (the *p* function in Figure 1) is not independent of the optimum capital-labor ratio. Given time, a change in the optimum ratio will affect not only increments to the labor force, but all of the previously existing labor force as well.[3] This means that when the optimum capital-labor ratio adjusts in an equilibrating fashion, the labor productivity function moves in a direction which is disequilibrating! In the case of deficient demand, for example, a rise in the marginal capital-labor ratio will raise investment and total demand; but as the new optimum ratio is gradually adopted throughout the economy the potential output of any level of the (fully employed) labor force is also increased. Only if demand rises more than supply will the adjustment be equilibrating.

Fortunately, however, we can expect the change in demand ordinarily to exceed the change in full employment output, so that, if the shift in the optimum capital coefficient alters investment in the right way, the perverse movement of labor productivity will not prevent the gap between total supply and total demand from being narrowed. This can be demonstrated by considering the case where the optimum ratio of capital to labor is doubled. This will double investment and total demand, but labor productivity will rise in a smaller proportion, provided only that the marginal productivity of capital is diminishing. Furthermore, since we are concerned with net output, we must take note of the fact that the proportion of the labor force engaged in replacement of capital will be higher with a higher capital coefficient. Thus, the rise in net output per worker will be smaller than the rise in gross output per worker.

It is possible, of course, that with the rise in real income per capita the ratio of saving to income will rise and total demand will fail to increase in the same proportion as investment. Offsetting this influence on the saving function, however, will be the change in income distribution resulting from the market forces (e.g., a rise in wage rates or a fall in interest rates) required to adjust the capital coefficient in an equilibrating fashion. For the prospect that labor's share in income will rise is enhanced by the perverse movement in labor productivity, requiring, as it does, a greater rise in wage rates (or fall in interest rates) to eliminate a given amount of unemployment.

[3] It is assumed for simplicity that this adjustment takes place as old equipment is completely amortized. The problems arising from a lack of correspondence between amortization and replacement are ignored in this paper.

On balance, then, it does not seem likely that the shift in labor productivity could be great enough to upset a tendency for the total adjustment to be equilibrating if the shift in the capital coefficient alters investment in the appropriate direction. Hence we will proceed on this assumption. Nevertheless, it should be clear that the tendency will be considerably weakened by the perverse movement of labor productivity.

We have yet to consider, however, just what modifications in the optimum capital coefficient will result from the market forces accompanying unbalanced growth. We turn now to a reconsideration of the theory of capital intensity for the answer.

II

One important result of the capital theory discussions of the thirties was the recognition that the influence of interest rates, wage rates, and prices on capital intensity depends on the nature of the limit to the firm's size. (Wage rates and prices refer to those expected over the lifetime of the investment.) It had theretofore been generally assumed that either a rise in the rate of interest or a fall in real wages, or both, would always reduce capital intensity, while changes in the opposite direction would raise it.

Nicholas Kaldor was perhaps the first to point out that interest rates will be the sole determinant of the firm's capital intensity when its size is limited by the market for its output; but when the supply of capital funds is the limit to expansion, real wages determine its capital intensity and the rate of interest has no influence. ("Capital Intensity and the Trade Cycle," *Economica*, February, 1939.) Unfortunately, Kaldor's results depend on the assumption of complete vertical integration in processes of production. (The assumption of complete integration is a natural pitfall for those who think of capital intensity as an average period of production. This makes Kaldor's adoption of this assumption even more surprising, however, for he explicitly rejected the period of production as a measure of capital intensity.) Furthermore, he was concerned with the capital intensity of the firm, not that of the economy. Changes in the composition of firms can change the over-all capital intensity even when there is no incentive for individual firms to alter their techniques. We shall proceed on the assumption that firms are nonintegrated (i.e., that they buy equipment from other firms and in addition only current labor). It is assumed that the services of equipment and current labor are the only inputs. And we shall take into account the effects on the economy's capital intensity of changes in the composition of firms. Finally, investment is assumed to be a continuous, synchronized process. (Cf. Friedrick and Vera Lutz, *The*

Theory of Investment of the Firm [Princeton University Press, 1951], page 33.)

We shall consider three limits to the size of the firm: sales, labor supply, and capital funds.[4] These, together with four market forces—changes in sales prices, wage rates, interest rates, and equipment prices—give us twelve possible cases for the firm which can be analyzed according to the following three rules: (1) profit maximization implies maximizing profit per unit of the limiting factor ("factors" include labor, capital funds, equipment, and sales); (2) a change in the price of a limiting factor will alter profit per unit of that factor equally for all methods, and hence optimum capital intensity is unaffected; (3) in all other cases, a change in the price of a nonlimiting factor will alter profit per unit of the limiting factor more for those methods which use relatively more of the factor whose price has changed.

All twelve cases are shown in Figure 2, where a zero indicates no change in capital intensity and a plus or a minus indicates, respectively, a change in capital intensity in the same or opposite direction to the change in the price of the factor.

		Limits		
		Sales	Labor	Capital Funds
Changes	Sales Prices	0	+	−
	Wage Rates	+	0	+
	Interest Rates	−	−	0
	Equipment Prices		−	0

FIGURE 2

If, for example, sales are the limiting factor, a change in sales prices will affect profit per unit of sales on all methods equally and cannot change their order of profitability. A change in wages, however, will alter profit per unit of sales (inversely) by a greater amount for those methods using relatively more labor. A rise in wage rates will, then, raise the optimum capital intensity. A change in interest rates or in

[4] Entrepreneurship has sometimes been suggested as the limit to the firm's size. For an effective argument to the contrary, see Tibor Scitovsky, *Welfare and Competition* (Irwin, 1951), pp. 190-193.

equipment prices will affect profit per unit of sales (inversely) more for techniques using relatively more capital. Thus a rise in interest rates (or equipment prices) will reduce capital intensity. The other cases can be worked out in similar fashion.

The crucial question is, then, what limits the size of the firm? This is not necessarily the same thing as asking what limits the growth of the economy. And it is fortunate for the prospect of automatic adjustment that it is not. For if labor supply limited the growth of the economy, for example, the resulting relative rise in wage rates would not induce a change to laborsaving methods if labor were also the limit to the size of the individual firm. The limit to the size of the firm depends, instead, on the imperfections in its product, factor, and capital markets. With no market imperfections there would be no visible limit to the firm's size (assuming proportional returns to scale).

Conceivably the supply of labor could serve as the limiting factor, particularly if the firm required a very specialized kind of labor. These cases are not likely to be quantitatively important, however, in a developed economy. Moreover, both kinds of unbalanced growth in our model are characterized by growing unemployment, ruling out a general shortage of ordinary labor. Nevertheless, for the less developed economies, the growth of some forms of enterprise may be checked by a shortage of skilled labor. Since this kind of economy is also likely to exhibit a deficiency of saving relative to the requirements of population growth, the case of labor supply as a limit might be appropriate in considering the adjustment to the excess demand type of unbalance. Due to limitations of space, however, we can treat adequately only the adjustment in the deficiency of demand case. Here, it will be assumed, the labor limit plays no important role.

The argument for capital funds as the limit to expansion of the firm depends heavily on the existence of uncertainty and the accompanying borrower's and lender's risk. Risk of bankruptcy and of wide fluctuations in earnings limits the ratio of borrowed capital to entrepreneurial capital from the borrower's side. Fear of loss of control limits the offers of new shares also to some proportion of entrepreneurial capital. From the lender's side, the insistence on reasonable security against the loan again limits the ability to borrow to some proportion of the firm's net worth. The availability of capital funds, then, is limited ultimately by the entrepreneur's own capital and this limits the size of the firm.

Some objections can be raised to this argument. First, uncertainty may be more specifically oriented than is often assumed. Instead of a vague, general timidity, uncertainty may reflect doubt about some particular aspect of the calculus involved in the investment decision.

If the doubt concerns some aspects of the expected performance of one method of production only, the risk premium should be deducted from the expected profits associated with that technique instead of being considered as affecting the supply of capital funds. Or, if the uncertainty applied equally to all techniques but is specifically uncertainty about the future volume of sales, this is properly thought of as a sales limitation on the firm's size. For capital expenditures which reduce the cost of producing a given output will not be impeded by uncertainty of this kind. There will undoubtedly remain, however, an important element of general uncertainty which cannot be related to any particular aspect of the investment decision; and this will be reflected in a reluctance to expand total investment beyond the limit imposed by entrepreneurial capital.

Still, there are good reasons for believing that the sales limit is more important in our economy, at least insofar as the capital-intensity decision is concerned. The large firms (which weigh most heavily in total investment) are fully aware of the obstacles to expanding their market shares and will often simply consider their growth as given by the growth of the market as a whole. Furthermore, they are usually in advantageous positions in the capital markets due to the lower degree of risk which normally accompanies large size, to their relatively great accumulations of entrepreneurial capital, and to the relative ease with which the dominant group can maintain control when the number of equity shares is increased.

Even with small firms, market situations where retaliation is expected are probably more prevalent than is generally assumed. Among many small firms selling similar products there will be local ("local" in the sense of product similarity as well as in the geographical sense) concentrations of more intense rivalry among a few. The sales limit seems, then, to be quite general in our economy, and we shall assume in the analysis that follows that this limit predominates.

So far we have considered only the capital intensity of the firm. But the average capital intensity of the economy can be affected by changes in the composition of firms even when there is no incentive to change the capital intensity of any single firm.

Insofar as different industries have different capital intensities,[5] market forces will affect their profits in varying degrees—but profits per unit of what? It is usually assumed that it is capital which moves to where its profit per unit is greatest, but this is correct only when

[5] We assume that all firms in the same industry are employing the some methods. This assumption is not essential, however. We could simply redefine an industry to include all those firms employing techniques of the same capital intensity, whatever they are producing. Then, general market forces will affect profits alike for all firms in the industry. The argument would proceed from there in exactly the same way.

capital funds represent the limit to the scope of the enterprise (because capital funds are limited by entrepreneurial capital). In the general case, it is the entrepreneur who moves from industry to industry and the incentive is maximum profits per entrepreneur. Wage, price, and interest changes will affect profits more in industries which have, respectively, high ratios of labor per entrepreneur, output per entrepreneur, and capital per entrepreneur. But there is no necessary relationship between these ratios and the ratio of capital to labor. Relatively high ratios of capital per entrepreneur and labor per entrepreneur within the same firm are perfectly compatible. Therefore, there is no presumption that these shifts will affect capital intensity in any definite way.

This would not be true if the capital funds limit were predominant in the economy. Since the capital funds limit is related directly to the size of entrepreneurial capital, maximizing profit per entrepreneur is equivalent to maximizing profit per unit of capital. Thus, whereas a rise in interest rates (or equipment prices) will not influence the optimum capital intensity for existing firms, it will shift enterprise away from those industries which have high ratios of capital to labor. Likewise, a rise in prices will pull enterprise toward those industries with high output-capital ratios; while a rise in wage rates will shift enterprise away from industries with high ratios of labor to capital. The necessary amendments to the table in Figure 2 can be accomplished by adding a minus wherever a minus or zero occurs in the third (capital funds) column and a plus where the plus occurs.

III

We are now ready to apply our theory of capital intensity to the case of chronic deficiency of demand. The first step is to establish what changes in prices, wage rates, and interest rates will occur when the growth of the labor force is insufficient to warrant capital widening equal to the flow of saving.

The unemployment due to the deficiency of demand will initially be accompanied by a redundancy of part of the capital stock. This will tend to reduce widening below the warranted rate and initiate a business cycle downswing. When the cyclical movement is reversed (for any of a number of familiar reasons), the pool of unemployed will permit capital widening to proceed in excess of the warranted rate in the upswing. Provided that the functions in Figure 1 remain unchanged, however, the fluctuations will tend to occur about an average trend as given by our crude growth model.

The only persistent element of disequilibrium in this situation is the growing (average) excess supply of labor. This means that wage

rates are likely to fall in relation to prices. The net effect of this on optimum capital intensity is likely to be disequilibrating (assuming sales to be the predominant limit to the firm's size; see Figure 2).[6] Only if interest rates fall sufficiently to overcome the perverse movement of real wage rates will the tendency for the capital coefficient to fall be absent. The "natural" movement of interest rates in this situation depends on what assumptions are made about monetary policy, which means that, in effect, there is no "natural" tendency in a state of chronic underemployment. In any case there are familiar reasons for supposing that beyond a point interest rates can be forced down only very slowly (at least with orthodox central bank techniques).

The tendency for adjustment in the capital coefficient in this situation to be disequilibrating results simply from the fact that a failure of the labor force to grow rapidly enough results (paradoxically) not in a labor shortage but in unemployment. Instead of rising real wage rates and the adoption of laborsaving techniques when the rate of growth of the labor force is too low in relation to the saving function, real wage rates fall and (in the absence of a sufficient reduction in interest rates) the capital coefficient adjusts in such a way as to widen the gap between saving and investment.

Though space limitations preclude an adequate treatment of the excess demand type of unbalance, it should be clear that here, too, real wage rates will tend to fall (as a result of chronic inflation accompanied by rising unemployment). In this case, however, the effect on the capital coefficient will be equilibrating (and will probably be reinforced by a rise in interest rates).

Before concluding, we should consider very briefly how the argument would be affected by relaxing the assumption of a constant state of knowledge. With growth of knowledge, labor productivity will rise (except as offset by diminishing returns due to fixed natural resources) and the optimum capital intensity may change in either direction or not at all, depending on whether the new, more profitable techniques use relatively more or less capital per worker than the previous optimum ratio. If we assume no population growth, the force behind expansion will be the labor freed as productivity rises. That is, over any period of time the labor force required to produce the average output of the period will diminish with the rise in labor productivity. If this freed labor is equipped with capital in the optimum ratio, causing capital widening just equal to the saving forthcoming from the income corresponding to full employment, there is balanced growth. This

[6] If wages and prices move in the same direction and in the same proportion, the effects on capital intensity exactly offset in this case.

freeing of labor can be represented by dL in Figure 1, and the problem of adjustment to unbalance is formally the same.

IV

Our conclusions can be summarized briefly:

1. Equilibrating adjustments in the optimum capital coefficient will normally be partially offset by disequilibrating movements in the labor productivity function; hence the market forces requisite to induce such an adjustment must be considerably stronger than would otherwise be the case.

2. However, given our assumptions (see 4 below), there is no natural tendency for the capital coefficient to adjust in an equilibrating way in the case of chronic deficiency of demand.

3. A situation favorable to automatic adjustment of the equilibrating kind in the deficiency of demand case would be inflexibility of money wage rates for downward (but not upward) movements combined with an easy money policy. An alternative would be a fiscal and monetary policy designed to promote capital widening in excess of the warranted rate; i.e., an overfull employment policy. For then growing labor scarcity would tend to induce shifts to laborsaving techniques (provided that interest rates were held down).

4. Our results depend on two important assumptions relevant to the theory of capital intensity: that firms are not vertically integrated and that sales represent the general limit to the size of the firm. If firms are vertically integrated, changes in real wage rates will not affect the optimum capital intensity for the firm in the sales limit case. (See Kaldor, *op. cit.*, pages 49-51.) If the supply of capital funds is the general limit, the results depend on the direction of movement of the over-all wage-price level as well as on relative wage-price changes and interest rates.

AN ECONOMETRIC MODEL OF GROWTH
U. S. A. 1869-1953

By STEFAN VALAVANIS-VAIL
University of Michigan

I

In the last generation we have seen theories of economic growth cast in mathematical form. Since the publication of the work of Professor Kuznets and Dr. Goldsmith, we are supplied with long-term statistics as well. I am referring to their contributions in the 1952 volume entitled, *Income and Wealth in the United States, Trends and Structure.* Mathematical theories plus statistical data invite econometric research.

This model adds to the short list of long-term estimating models (other such: Tinbergen, Kalecki). It is the first to employ simultaneous estimating techniques. It has been extrapolated one period with satisfactory results; it can be used to test certain economic hypotheses and to derive the dynamic properties of the American economy.

Summary of the Model. Table 1 lists the variables and definitional identities. Table 2 shows the estimated structural relations. There are twelve structural relations and eight identities and twenty endogenous and seven exogenous variables. A brief picture of the economy follows: (1) Consumers' (including government) and producers' demand outputs. (2) Manpower-producing families and capital accumulators supply the factors of production. (3) Labor, entrepreneurs, landlords, and the financial sector claim income shares. (4) The factors of production are transmuted into the outputs demanded by means of a production function. (5) The actual factor-blend used in production depends on relative costs in the manner shown by a "substitution function." (6) The distribution of income is attained by bargaining and held within limits by occupational mobility. New manpower flows so as to prevent too great a disparity of average per capita income from one occupation to another. (7) To the real flow corresponds a counterflow of money, whose quantity is controlled by the government and the financial sector. Money influences the price level and this in turn affects distribution. The degree of activity (or wealth) and the quantity of money together determine the interest rate, which in turn affects capital accumulation.

The model derives its dynamics from lags (see Table 2, equations 4 and 8), but also from the use of time as a variable (equation 6). Other dynamizing devices are found in the cumulative nature of the

variables K and J (they are defined in Table 1, bottom) and also in the generous use of relative variables; for instance, those with K or J in the denominator.

Problems Specific to Long-term Econometric Models. Over and above the usual difficulties of econometric investigations, the building of long-term models presents special difficulties.

TABLE 1

LIST OF VARIABLES AND IDENTITIES

(All units are in annual averages for the decade, unless otherwise indicated. Stock variables are as of the midpoint of the decade.)

	Endogenous Variables	Units		Endogenous Variables	Units
b	Birth rate	Number per 1,000 of population	w	Money wage rate	1929¢ per hour
			Y	Gross real output	b—1929—$
C	Consumption	b—1929—$	e	Labor input	billions of man-hours per year
D	Depreciation	b—1929—$			
E	% of N employed	full employment = 100			
				Exogenous Variables	
F	Financial income	b—1929—$			
			d	Death rate	number per 1,000 of population
I	Gross investment	b—1929—$			
i	Long-term interest rate	% per year			
			h	Standard hours	hours per week
J	Population	millions	L	Value of land	b—1929—$
J^*	Population over 15	millions			
K	Stock of capital	b—1929—$	M	Money	billions of $
N	Labor force	millions	m	Net immigration	1,000s per year
			t	Time	1869–78 = 1, 1874–83 = 2 &c
N_π	Entrepreneurs	millions	U	% of N_W unionized	per cent
N_W	Wage earners	millions			
p	General price index	1929 = 100		**Error Terms**	
Π	Entrepreneur income	b—1929—$			
R	Rental income	b—1929—$		u or $u_1, \cdots u_{11}$ random shocks	
W	Real wage bill	b—1929—$			

Identities

(I 1) Output	$Y=C+I+D$
(I 2) Income	$Y-D=W+\Pi+R+F$
(I 3) Capital	$K=K_{-2}+10(I-D)_{-1}$
(I 4) Population	$J=J_{-2}+.01(b-d)_{-1}\cdot J_{-2}+.001m_{-1}$
(I 5) Labor force	$N=N_W+N_\pi$
(I 6) Money wage rate	$w=Wp/52EhN_W$
(I 7) Labor input	$e=52\times10^{-6}EhN$
(I 8) Population 15+	$J^*=J_{-3}(1-.01\cdot d_{-3})(1-01\cdot d_{-2})(1-.01\cdot d_{-1})+.01\cdot m_{-2}(1-.01\cdot d_{-2})(1-01\cdot d_{-1})+01\cdot m_{-1}(1-01\cdot d_{-1})$

The present state of our historical statistics compels us to build long-term models of rather frugal proportions. A model should involve a small number of variables, because several of the available statistical series rely on one another—this being particularly true of the earlier years. Too many interdependently constructed series produce fictitious

correlations. Few variables per equation should be used, because over a period of growth all variables increase (or decrease) several times their initial values and thereby exhibit a superficial intercorrelation that overwhelms finer structural relationships. Several well-intercorrelated variables in a single equation yield regression parameters of shaky statistical significance. Example: In the production function of Table 2, capital, output, and labor all increase substantially with time. Time and capital are so well correlated that it is impossible to introduce both in the production function and still obtain reasonable sampling error. Finally, a long-term model should contain a small number of equations, because if the few variables it contains are brought again and again in a great many equations they may eventually produce lack of identification.

Lags and other similar devices (integrals, derivatives, accelerators, maxima, and minima) are almost indispensable for self-powering dynamic systems and are used very extensively in ordinary econometric models. But in long-term models it is often not legitimate to use these devices. We have more changing sets of people and firms, a dimmer memory of lagged variables, and a shorter inertia in behavior if we pass from decade to decade than from year to year. Naturally the optimum lag may itself be among the unknowns to be estimated. This would be possible if annual data were available though at the cost of lengthy computations.

We are cautioned, therefore, to use sparingly derivatives, lags, and other traditional devices that give dynamic patterns. But then how

can we describe the exponential, logistic, and other dynamic patterns typical of most long-term statistics?

First, it happens that certain relationships materialize if allowed enough time. For instance, the accelerator's constraint (spurious in the short run where you have excess capacity, overtime, and double shift as good alternatives to new investment) is the more likely to become felt the longer the period considered. I find it much easier to believe in a long-run accelerator than in its frantic short-run version. Second, to dynamize a model we may use "floors," "ceilings," targets, and other critical values obtained from technology or psychology. When a uniformly developing system (growing or decaying) hits a floor or ceiling, it is forced to alter its velocity of development, thereby causing a realignment of other variables by accelerator-type effects. Another dynamizing device is the building into the system of several potentially conflicting trends, like the simultaneous decrease in both the birth rate and in the death rate, or the simultaneous tendency for the labor force to increase and for weekly hours to decrease. Critical points when crossed alter the direction of growth in some part of the system—say in employment or distribution—and soon propagate disturbances throughout the system.

Like any econometric model, a growth model can also be dynamized by means of exogenous shocks. Exogenous variables are of two kinds: economic and noneconomic. The more noneconomic exogenous variables, the better. The fewer economic exogenous variables, the better. Shock-type changes occur in particular times and not in others for good reasons, some of which are to found in the process of development itself.

So much for the difficulties of long-term econometric model building in general. Now there are some special ones due to the nature of my data and the extent of my computing resources. The Kuznets and Goldsmith data, used in this study, come smoothed out in the form of decade averages overlapping five years. The first decade is 1869-78, the second is 1874-83, and so on. For consistency, the data derived from other sources were reduced to the same pattern of fifteen overlapping decades from 1869 to 1948. Averaged series are generally fictitious—meaning by this term that the variable in question seldom assumes a particular average value. Now it can happen that a particular value is a critical value; for instance, a "warranted" rate, or an equilibrium point, which, had it been hit, would have had special effects. The data used in long-term models are as a rule more drastically averaged than data used in short-term models, and therefore the long-term model is more likely to miss essential information from our deliberately ignoring the critical points. Suppose that we did possess annual, quarterly,

weekly, or daily data. We could proceed in two ways: average the data and then estimate the equations or estimate the equation and average the result. Unless all the series and functions are extremely well behaved, there is no guarantee that the two methods will give outcomes that agree. Further, in disregarding these possibilities we are postulating something akin to a "law of continuity" of behavior and brushing aside the whole question of whether cycles are organically connected with growth. So both the fact that averaged data are used and the fact that these averages are decade (and not some other) averages qualify the results and restrict the uses of my model.

Estimating Procedure. The parameters of this model were estimated by the limited-information–maximum-likelihood method. Those of you acquainted with the vicious algebra of the method may ask: why now use such an elaborate and refined method for crude data, rough approximate relations, and with so few degrees of freedom? The answer is that this method captures the spirit of simultaneity underlying the economic system that the model is supposed to describe: it treats all the variables on equal footing, avoiding cause-effect decisions between endogenous variables. In this sense the method is free of theoretical bias. The method is unbiased in the statistical sense as well (for large samples). However, I did not use the maximum-likelihood method in the full glory of its general form. Certain assumptions were made in order to simplify the computations.

1. The disturbances u were assumed to be non-autocorrelated in each equation. This overstates the efficiency of our estimates by pretending that the fifteen observations are independent. To see this, take a linear equation of the form $\beta y_t + \gamma z_t = u_t$ where β, γ are vectors of the unknown (constant) parameters, y and z vectors of the endogenous and of the predetermined variables and u_t the random disturbance at time t. It follows that $\sigma^2_{\Delta u} = E(u_t, u_{t-1})^2 = \beta E(y_t, y_{t-1})^2 + \gamma E(z_t, z_{t-1})$. Where the y's and z's are period averages overlapping half a period, they have a serial correlation of ½. Therefore $\sigma^2_{\Delta u} = 0.5(\beta + \gamma)$, a fact which should be taken into account, except that β and γ are unknown, considerably burdening the computations. The first simplification then was to set $\sigma^2_{\Delta u}$ equal to zero.

2. *Linearity.* The numerous nonlinear variables such as, in Table 2, $e = 52 \times 10^{-5}\, EhN$ $\frac{I}{K}$, $\frac{Yp}{M}$ contained in the model were treated equation by equation as if each were a simple variable, no correction being made in the estimating procedure to take account of these nonlinearities. Though it violates the strict requirements, this disregard of nonlinear variables leaves unaffected the statistical efficiency of my limited

information estimates. The alternative was to make the model strictly linear. Two reasons decided against it. First, the particular compound forms used are supposed to have economic and behavioral significance; e.g., e is the "labor inputs," $\frac{\Pi}{K}$ is the "rate of profit," and $\frac{Yp}{M}$ is "income velocity of money." Second, linear approximations generally necessitate a larger number of parameters to be estimated and I felt that I ought to economize the few degrees of freedom I dispose of. The model is linear in the parameters; and there are no side restrictions on the parameters.

3. An essential feature of the maximum-likelihood methods (with full or limited information) is to let each predetermined variable affect not only the parameter estimates of that equation in which it enters explicitly but of all other equations in the model as well. The common-sense equivalent of this property is that an exogenous shock or a lagged endogenous value permeates from end to end the simultaneous system of the total economy; computationally this is done by bringing into the estimation of each equation the matrix M_{zz} of moments of all the predetermined variables (z_i) in the entire system. But in fact the capacity of my computing equipment forced me to use only an arbitrary subset of the predetermined variables. This is the third simplifying assumption.

4. The fourth is the use of limited information. The method does not allow the parameter estimates of one equation to affect those of another. Adding, dropping, substituting, linearizing, or delinearizing a variable in one equation leaves unaffected the parameter estimates of another. Adding or removing an entire equation has no effect on the balance of the model. This means that if we wish to experiment cheaply with alternative formulations of given structural relations, we can do so under the limited-information method. In exploratory studies, the flexibility advantage of the limited-information method overweighs the disadvantage of suppressing some information. Since I think we know a little, a priori, concerning the form and number of independent long-term structural relationships, I am not so urgently interested in observing the modifications in one function brought about by some change in another or those brought about by dropping or adding an equation.

II

Evaluation of the Estimates. Though theory states that a certain relation exists, the particular econometric form of it that we adopt is reached by "cut-and-try" methods. A version is satisfactory if it combines a reasonable value of a parameter, small variance, and accuracy

in prediction. The first two qualities can be observed directly from Table 2.

In adopting this rather than that formulation, I have sometimes used a combination of arguments based on theoretical principles, on statistical necessity, and on expediency. This I frankly admit and, if you will, I may justify it in jargon by saying that with scarce and crude data, limited computing resources, and as yet undeveloped statistical techniques, what I did was to equalize at the margin the benefits from arithmetical minuteness, statistical subtlety, and theoretical rigor. You do have to sell your soul in the econometric business of today unless you have at your disposal tailor-made data and vast computing resources.

The results sometimes confirm and sometimes contradict accepted economic hypotheses. In view of all the inadequacies, the ability to confirm or contradict an economic hypothesis does constitute a step forward. In fact, I can do a little more; namely, predict in a limited sense.

Extrapolation of the Model. Estimating the model was begun in 1951, when only fifteen decades of data were available. At present, however, we have some data for a sixteenth decade (1944-53) and by means of them we can evaluate the predictive power of the model. The system of Table 2, if solved simultaneously, reduces to a ninth degree equation in Y. Inserting values for the predetermined variables, Y can be forecast, and working backwards all the other endogenous variables can be forecast too. To avoid this laborious task and yet be in a position to say something about the predictive ability of the model, I have proceeded in the opposite manner. I have obtained rough estimates for the years 1944-53 for all the variables, both endogenous and exogenous. These were inserted in the structural equations and they yielded certain residual errors for the decade 1944-53. These residual errors, in percentage form (Table 3), can be compared with the residual errors of the sample period. They should not be compared from column to column.

Actual investment (Column 5) is 64 per cent over the estimated but this is not surprising in view of the intervening world war and the investment boom it brought with it. Financial income was 10 per cent *larger*, and rental income 26 per cent *less* than "forecast"—probably due to wartime speculation and rent controls.

In the remaining equations, the model extrapolates to 1944-53 at least as well as it fits the sample period 1869-1948.

Implications of Our Parameter Estimates. In Table 2, I exhibit a linear homogeneous version 1 and a Cobb-Douglas version 1′ of the production function. The latter reverses the relative size of the contribution of labor and capital found by Douglas. We must remember,

however, that Douglas' study is for manufacturing only while mine is for the whole economy, and there is relatively less capital in the sum total of productive activities than in manufacturing industries. Secondly, Douglas' figures for labor input include wage earners only, while mine include the entire labor force; so my labor inputs, the variable e, are always greater than Douglas' N (in absolute terms) and my K is always less than Douglas' K (in relation to the labor inputs). Thirdly, there is no reason why the long-run marginal productivities of labor and capital should not differ from the short-run.

It is interesting to note that the sum of the exponents of 1′ approximately equals unity, something akin to the Cobb-Douglas homogeneity hypothesis, only now for the long-run global production function. This implies that if income were distributed according to marginal productivity, the product would be exactly exhausted; if distribution does not in fact agree with the marginal principle, we ought not to blame the production function. Let us look at the marginal productivities in Table 4. Those of labor and capital have been computed from the production function and in Table 4 have been listed along with the real wage and the profit rate. In both cases the marginal hypothesis seems contradicted. Labor appears to be 1½ to 2 times "overpaid" while capital is persistently 3 to 5 times "underpaid." Before concluding too much from this we should remind ourselves that: the labor inputs in the production function relate to the entire labor force, while the wage rate relates merely to the wage earners; our statistics do not record the increasing skill, health, and education as additions to the labor inputs but as forms of capital (schools, hospitals, churches) and thereby understate the productivity of labor; many things can happen in aggregating over firms and industries to obtain a global production function. The fact that the latter turns out to be homogeneous of degree 1 is no proof that the individual production functions are too. It is possible that each industry or firm equates wages to the marginal product of labor, but that monopolies or fixed input-output requirements of one industry from another prevent the marginal product of labor from reaching a uniform level in the entire economy. Therefore the statistics carry no implication that in any one firm or industry labor gets more than its marginal product. For the underpayment of capital, there are a number of fancy explanations: British predilection for investment in America; cheap money agitation; managers maximize size of business; they make consistently overoptimistic estimates, and others which do not diminish my astonishment at the unexpected results of Table 4.

Professor Arnold C. Harberger offers the following pragmatic solution: We know that the various income shares show remarkable stabil-

ity over a long period of time; that, at least in the long run, there is competition both in the product and in the factor markets; that there has been technological progress. Therefore we should utilize this knowledge to fix the exponents of our Cobb-Douglas production function at some reasonable level and from this estimate the remaining unknown; namely, the contribution of technology.

If we use as exponents the average value of the factor shares, as in Table 4, $av\ (W/Y) = .540$, $av\ (\Pi/Y) = .177$, $av\ (R/Y) = .074$ we

TABLE 4

MARGINAL PRODUCTIVITIES, REMUNERATION OF LABOR AND CAPITAL, AND INCOME SHARES

Equation 1″: $Y = .72K^{.177}(52 \times 10^{-5} EhN_W)^{.54} L^{.074}(1.08)^t$

obtain by least squares the formula 1″ (Table 4, bottom), where .72 and 1.08 are the estimated constant factor and the technological growth factor, respectively.

Eight per cent per decade is equivalent to about ¾ of 1 per cent (cumulative) per year. This rate is not unreasonable for that part of growth not due to increase in labor force or to increase in capital.

Elasticities. Table 5 shows point estimates of the various elasticities connected with the production function: They are defined as ratios

between the logarithmic derivatives of Y, e, and K. The three columns present the output elasticity of labor inputs (capital held constant), the output elasticity of capital inputs (labor held constant), the elasticity of substitution of labor for capital (output constant). The ratio of two values of ηeK for two decades is identically equal to the ratio of the values K/e for the same two decades. Similarly, the trends of ηYe, ηYK are average productivity trends Y/e, Y/K.

We notice that the elasticity ηeK decreases quite rapidly with time and this indicates that the economy produces a given output in more

and more capital-intensive ways. In the decade 1939-48, for instance, a 1 per cent increase in capital would have (for the same output) displaced 9 per cent labor, while in the decade 1869-78 it would have displaced only 1½ per cent labor. These comparisons are significant only to the extent that the linear production function 1 (Table 2) fits the data well. As a matter of fact the exponential form 1′ fits them better and its elasticities are constant over time.

The "substitution function" (equation 2 in Table 2) has two aspects. First, it is a technological relation. Though particular firms or particular industries may operate under fixed coefficients of production, by substituting process for process or industry for industry, we can in the aggregate technology speak of substituting labor for capital. As for any firm or industry, so, too, for the aggregate technology, there are limits to substitution. Second, the function describes an economic

relation. It determines which factor-mix out of the many possible will be actually employed, and (equation 2) tells us that more capital will be used the higher the real wage rate. For instance, if the level of capital is 360 billions of 1929 dollars and wages are 63 real cents per hour, then a 10 per cent increase in real wages will lead to a 4 per cent contraction in labor inputs; at the same level of real wages and capital a 10 per cent increase in the capital stock would require a 4 per cent increase in labor inputs.

Turn to the first version of the investment function (equation 5). It implies that a one-point rise in interest brings the rate of investment down by roughly one-half of a percentage point. As our equation is linear, we cannot use it to test the interesting speculations whether investment exceeds all bounds at near zero interest rates. The alternative version (5′) is an accelerator type. From the substitution function, we can compute the amount of capital that is best for any given level of output, real wages, and labor. Investment is determined by the attempt to adjust capital to the appropriate level K_{req}. Equation 5′ says that the rate of investment is more than seven times the rate of capital shortage.

The dynamics of the birth rate (equation 6) are straightforward, with the variable t (time) summarizing all the sociological and ecological trends that pull down the birth rate. Shorter run fluctuations in the birth rate are related to prosperity and depression. Other things being equal, one more baby per year is added to each 1,000 of population for every 9 per cent annual increase in per capita real income. To maintain the birth rate at any realized level requires an average increase in per capita real income of 11 per cent annually.

Equation 12 confirms the hypothesis that people choose to take part of their progress in leisure for more individuals, in addition to more leisure for a given number of individuals which is reflected in the decline in working hours.

Equation 7 shows how the total labor force divides itself into its two main occupational categories: the wage earners and the self-employed. It is not necessary for every worker to have occupational choice but that there be a marginal group having mobility. If mobility were perfect and income the only consideration, the constant term of the equation would be zero and the second parameter of equation 7 equal to one.

We have discovered that the global production function cannot explain the factor shares by means of the marginal productivity theory. The wage bargain equation 8 formulates the common-sense view that wages depend on prices, on the power of the unions, and on the degree of prosperity.

The Monetary Equation. In equation 11, I have expressed Kalecki's theory of long-term liquidity preference, while equation 11′ is an asset preference ratio theory of money balances. M is monetary assets of the nongovernment, nonbanks public. The curvature is as expected. The richer the community the greater the proportion of its assets it can afford to hold in liquid form.

III

Dynamic Properties of the Model. To show the derivation of the model's dynamic properties is a laborious task. I shall limit myself to telling what the results are.

The Long-run Multiplier and the Domar Problem. In solving for equilibrium conditions, we find the long-term marginal propensity to consume very close to unity. At most, 23 billion 1929 dollars of autonomous, unproductive, net investment are required annually to maintain employment equilibrium. If, however, the required investment is all productive, since it raises output in the future, it must increase at the rate of 3 per cent per year, assuming constant population and constant labor force. If, as is predicted by population experts and sociologists, the labor force percentage should continue to increase for two or three decades more and then become stabilized while population continues to rise at the present rate, the rate of growth in the required investment is considerably smaller than 3 per cent in the long run, and perhaps the savings gap will close by itself.

The Inflationary Bias. The income distribution and the monetary equations solved simultaneously as a subsystem reveal that if other things remain equal an autonomous rise in the price level leads to a sharper rise in the equilibrium money wage.

The financial income equation (9), disregarding the constant, says that roughly three-quarters of the value of capital yield financial income. This is in agreement with the fact that approximately 20 per cent of total capital is social capital (roads, monetary silver, and gold) which does not yield financial income.

Similarly, not all land yields "rental income." Public land must be subtracted: it is about one-fourth of the total in acreage, though it is hard to say what percentage it is in value terms. About 40 per cent of homes and farms are owner-occupied. The rest are rented but their yield is not counted in rental income unless the proprietor engages primarily in real estate. As a rough guess about one-third to one-fifth of the leased land belongs to this category. All in all, rental income yielding land should be in the neighborhood of two-thirds of the total. This, too, agrees with equation 10.

Conclusion. This simplified account of my study shows that for broad

purposes, one set of a dozen or fewer equations captures the outline of the American economy over a long period of time. In spite of laborious compilation of data and refined manipulations of time series, I have admittedly contrived only a rough sketch of the American economy. But there is some satisfaction in the very roughness of the task. By tapping only the more accessible surface riches of our new statistical series and by testing econometrically only for the bolder generalizations of "magnificent dynamics," one is rewarded with easy victories. As you see, it is possible to get some stable estimates with reasonable implications and with predictive ability. If I am to evaluate the general significance of my work myself, the most modest conclusion I can draw is this: Pessimists, cheer up! It *can* be done!

DISCUSSION

Evsey D. Domar: Mr. Power's paper is in two parts: the first is concerned with the relationship between the growth of the labor force and general economic growth and stability; the second is devoted to the study of the effects on capital intensity (that is, the ratio between capital and labor) of changes in the interest rate and in the prices of labor and of capital equipment. An analysis of these effects is required for the solution of the problem raised in the first part.

The first part presents a growth model consisting of four simple equations:

$$(1)\quad I = c\,\frac{dL}{dt}\,;$$

$$(2)\quad S = sY\,;$$

$$(3)\quad Y = pL\,;$$

$$(4)\quad I = S\,,$$

where c stands for capital intensity, s for the fraction of income saved, p for average labor productivity, and I, L, S, and Y indicate investment, labor force, saving, and income, respectively.

The solution of this system takes the form of

$$(5)\quad \frac{\frac{dL}{dt}}{L} = s \cdot \frac{p}{c}\,.$$

In other words, under the assumed conditions, there exists an optimum rate of growth of the labor force which will just assure sufficient investment for the maintenance of full employment; and a deviation, up or down, from this rate will result in a cumulative process of inflation or deflation respectively.

The structure and solution of Mr. Power's model are so similar to those of the investment models of Harrod, Fellner, and others (and it can be easily shown that the capital coefficient used in the latter is but c/p), but one may wonder what special purposes it serves. I believe there are several.

It allows the builders of other growth models to see their creation, so to speak, from another side, which may give rise to some second thoughts. It is obvious that constancy of the capital coefficient implies constancy of the ratio between capital intensity and labor productivity (c/p); yet this had not occurred to me.

Mr. Power's model shows how an attempt to equip a rapidly growing labor force with sufficient capital equipment can simultaneously create inflation and unemployment—a phenomenon not unfamiliar to students of undeveloped countries. But the fact that the remedy lies in a higher propensity to save may be of interest to some of our more devout Keynesians.

Finally, the model makes explicit the conditions which give rise to a most interesting paradox in the theory of growth; namely, that an insufficient

growth of the labor force can cause the unemployment of labor—a paradox mentioned by a number of writers but usually without the naked simplicity of Mr. Power's model. (See the discussion of this subject by D. Hamberg, H. Pilvin, R. F. Harrod, and E. D. Domar in the *Quarterly Journal of Economics*, August, 1952, pages 444-449; November, 1953, pages 545-563; and November, 1954, pages 641-648.) They have been concerned that an attempt to invest all the savings which the public desires to make would cause an over-accumulation of capital, presumably relative to available labor, and that the capital thus made idle would lead to a fall in investment and hence in national income and employment. This presupposes that the ratio between capital and labor (capital intensity) is fairly rigid, and I cannot help wondering if all those who have used this paradox as an explanation, or at least one of the explanations, of the downswing are also willing to subscribe to the assumption on which it is founded.

To raise a question of this type may well be the main purpose of simple mathematical models: they hardly describe reality, nor can they predict, but they may induce the general economist and the man of affairs to give a second thought to a position previously taken.

The second part of the paper deals with capital intensity; that is, with the ratio of capital to labor. This is indeed a most interesting subject the importance of which transcends its use in this particular model. It is not a new subject in economic literature but unfortunately it has been mostly used (or may I say misused) in business cycle theories. (See the discussion and bibliography in Friedrich and Vera Lutz, *The Theory of Investment of the Firm* [Princeton, 1951], pages 137-142.) Let me put cyclical considerations aside and restate the problem in the following manner: why does it pay to use American machinery produced with expensive American labor to save other expensive American labor, while it frequently does not pay to use, say, Japanese machinery produced with cheap Japanese labor to save other cheap Japanese labor? If Japanese machinery were used to replace American labor, the answer would be obvious; but the shoe is on the other foot, and quite often it pays to use American machinery produced with expensive American labor to replace cheap Japanese labor. My question undoubtedly sounds naïve, and the answer may be perfectly obvious; but I must confess that it escapes me, at least in the more or less static setting of Mr. Power's model, which does not include an analysis of technological progress as such.

Abstracting from the latter, we can reduce the question to two simpler ones: will a fall in the interest rate and a rise in wage rates increase capital intensity; that is, bring about the substitution of capital equipment for labor? If wages rise relatively to prices of capital equipment, the answer is obvious (I hope). This is the assumption that Mr. Power uses, but I have doubts whether it is fully justified on empirical grounds if sufficient time is allowed, as it should be in a secular problem, for the completion of all adjustments. From an analytical point of view, the other possibility—that prices of labor and of capital equipment rise at the same (relative) rate—is of course much more interesting.

For the solution of this problem, we are referred to Kaldor's article on "Capital Intensity and the Trade Cycle." (*Economica,* "New Series," 1939, pages 40-66.) It is a most interesting paper (though I do wish that its author, having shown his well-known analytical virtuosity in the body of the paper, would then have added an appendix for the general reader). Two cases are considered: (1) when the size of the firm is limited by capital funds, and (2) when it is limited by the extent of the market for its products. In the first case, Kaldor reaches the surprising—at least at first glance—conclusion that capital intensity will not be affected by changes in the interest rate, because, by assumption, every project considered by the firm requires the same amount of capital. The latter is really rationed, and hence its price is of no importance, unless it rises high enough to make this assumption ineffective. On the other hand, the amount of capital being given, a more capital-intensive project uses less labor and has a smaller output and hence a larger profit margin per unit of output than a less capital-intensive one of equal profitability. Therefore an equal proportionate rise in prices and in wages will discriminate in favor of a more capital-intensive project.

Kaldor's second case assumes an unlimited supply of capital funds but a limited demand for the product. The conclusions of the first case are now reversed: the interest rate is effective because the capital-intensive project uses more capital; but an equal (relative) change in the prices of both labor and capital equipment is of no importance because two equally profitable projects have identical cost curves. Kaldor's whole discussion is based on the assumption of constant returns to scale.

Kaldor's two special cases (and they are quite special) only whet one's appetite rather than satisfy it, but an excursion to *The Theory of Investment of the Firm,* by Friedrich and Vera Lutz, where a number of possibilities are analyzed in great detail, does not resolve the problem either, particularly as far as the change in prices of labor and of capital equipment is concerned (the authors are somewhat more positive regarding the effect of the change in the interest rate); and we are told that depending on the exact nature of the profit-maximization process and on the shapes of demand and cost curves and other conditions, the effect on capital intensity can be in either direction. And this is odd, because the greater capital intensity in the American economy as compared with others appears to be so clearly established that a reasonably unequivocal explanation of this phenomenon should be forthcoming.

The problem surely deserves further study, and I hope Mr. Power will continue working on it. May I make a few very simple suggestions:

1. It is about time to start distinguishing between a firm and an industrial process or a project. The amount of capital funds available to a firm may be given, but not necessarily to each project. On the other hand, the market for a particular product may be limited, but a firm can create new products. (On this see Edith T. Penrose, "Limits to the Growth and Size of Firms," in this volume.)

2. Similarly, it is about time to stop the identification of funds available to a firm with its investment in capital equipment. Funds are obtained not only for such investment but also to buy raw materials, pay wages and taxes,

and make all sorts of expenditures. After all, capital equipment is not always bought; it can be rented.

Finally, I suspect that we shall make little progress in this field without a closer analysis of technological change and without an explicit recognition of uncertainty.

T. C. SCHELLING: My comments relate, first, to the structure and, second, to the perspective in time of Mr. Valavanis' model.

In making the acquaintance of a twelve-equation model it is sometimes helpful to look for familiar, simpler models embedded in it, being on guard against the dangers in taking a submodel out of context.

We can ask, for example, what in the model makes income grow. A complete answer depends on the whole system of equations and even to describe how it grows requires a ninth-degree equation. Still, the main engine must be simpler. There are only two demand equations for final goods—consumption and investment—and they must be central to the growth process.

In the consumption equation, population explains a rising level of absolute consumption but not the rise per capita. The high long-run propensity to consume, however, of about 100 per cent, needs only a little investment to become explosive; and the lag, by holding the "current" propensity to about 70 per cent, strongly damps the explosion. (If investment followed a simple relationship to income, for example, the growth formula would be approximately $Y = [30/(30\text{-}v)]Y(t\text{-}1)$, with v denoting the propensity to invest and the lag being a complicated average of about five years.)

The Valavanis investment equation can partly be construed as a "propensity" related to profits; if we multiply through by $K/100$, one term is "income minus wages." But then it also has a term equal to the capital stock times a constant plus the interest rate. While the interest rate component could be interpreted here as a refinement of profits to a net "after-interest" basis, the negative effect of the capital stock on investment strongly suggests the acceleration principle rather than a propensity to invest out of profits.

The acceleration principle emerges quite clearly if we treat the interest rate as a constant, and consider $(Y\text{-}W)$ as a constant percentage of Y. The whole investment equation than translates into

$$I = a[kY\text{-}K]$$

where k can be interpreted as the "normal" capital/output ratio, and the parameter, a, reflects the rate over time at which investment tends to bring capital stock into normal relation to output. This is pure acceleration principle.

The interest rate is not in fact constant; but its variation over the period exerts little leverage in the Valavanis model. The constancy of $(Y\text{-}W)$ in relation to Y can be improved by inclusion of a time trend that would not be hard to rationalize in the acceleration relationship.

Whether investment is really acceleration-motivated is not proven by the fact that this translation can be made; and I doubt whether the "correct" structure of an investment equation will ever be discerned in such highly aggregative time series data. What the translation shows is that investment,

income, and capital grow, in the Valavanis model, as if a familiar multiplier and accelerator yielded nicely damped explosive growth over the eighty-year period.

Probably any pattern of actual growth is bound to look like a multiplier-accelerator model over the long run, and we must not deduce too much motivational significance from the appearance. But it does help acquaint us with the mechanics of the present model to see its close quantitative analogy with the familiar machine. Incidentally, the strong consumption lag in the Valavanis model yields an unusually stable mechanism of accelerator growth.

We did not ask above whether the parameters of this accelerator model yielded growth rather than cycles. They do, but since they were fitted to a period of actual growth, their values were nearly bound to. But we are naturally tempted to inquire how close they are to yielding cycles, and to manipulate the model in various ways to see whether shocks can lead to cycles, or how price inflation works through the system, etc. Unfortunately, most such interesting questions have to be ruled out of order, for reasons that lead to the second part of my comments—on the statistical timing of the model.

The data from which the model is derived are decade averages, spaced five years apart. There can be no business cycles in such data, except very long ones or such greatly damped and distorted ones as emerge from the averaging process. Similarly, the model cannot generate any cycles but very long ones. Even ignoring the averaging process, the shortest time interval is five years. And the only inflationary process that can be traced through the model is, consequently, one that emerges from long-run wage trends.

But what good is a model that cannot generate business cycles? This question is asked not because we are interested exclusively in cyles but because business fluctuations in the period covered by the model have been of such importance that we must question any analytical scheme that is inherently incapable even of recognizing those that occurred.

The above question is not purely rhetorical. Whether the model is valid depends a good deal on whether long-run economic development in this country has in fact been essentially long run in its behavior dynamics or has been instead the continuous compounding of essentially short-term behavior. If we knew—on the basis of knowledge other than long-run time series—that investment decisions were mainly related to current or short-term factors, then a long-run model might reflect some kind of average behavior; but it would probably be fairly unreliable for analysis or prediction, it could differ greatly from the "true" structure of the system, and it would probably yield no information about the motivation of investment at the level of the individual firm.

I would emphasize that this question about the Valavanis model is not the usual one of long- versus short-run determinants of growth. The model is not just long run; it is long-run and highly endogenous in its mechanics of growth. It does not incorporate trends, with the main exception of population. It is a self-propelled machine that ignores the intradecade bends in the road and navigates from a minimum of secular benchmarks. So our full question should read: can we abstract both from the endogenous short-term dynamics

of the American economy and from the long-term exogenous trends, and find a substantial body of long-term endogenous relationships that are not only valid but so influential that they govern, decade by decade, the long-run pattern of growth?

Mr. Valavanis' hypothesis is that we can; and, within the limitations of aggregative time series correlation, his results are some test of that hypothesis. Unfortunately, until some annual data are reconstructed for the same period, a competing hypothesis relying on shorter term behavior dynamics cannot be fitted for comparison.

CURRENT PROBLEMS IN AGRICULTURAL ECONOMICS

THE SUPPLY OF U.S. FARM PRODUCTS UNDER CONDITIONS OF FULL EMPLOYMENT*

By EARL O. HEADY
Iowa State College

Appropriate quantitative estimates of the agricultural supply function under full employment do not exist. However, some writers have suggested that either the elasticity is zero or that the variables underlying the supply functions are entirely exogenous to the economic system.[1] While agricultural production does not vary greatly between years, the elasticity coefficient is certainly greater than zero.

Full interpretation of the agricultural supply function in an environment of full employment can be made only with several years of complex empirical research including: (1) specification of the appropriate analytical model (i.e., the relevant variables and their possible algebraic forms); (2) measurement of the relevant observations; and (3) prediction of the coefficients which make up the system of equations involved. These empirical predictions are difficult over a period which encompasses the full range of variations in employment; perhaps they are impossible for the smaller number of time-series observations which represent the relevant span of full employment. The period of years which provides the framework for observing the agricultural supply function under full employment is both short in years and heavily confounded by other phenomena. The only two periods of full employment which are meaningful for our purposes are 1910-29 and 1942-54. Even then, half of the first period represents one in which the agricultural plant was still being expanded by the addition of cropland and total farm acreage. Also, a war emergency existed in both of these periods; nonprice restrictions and incentives cause these years, as well as some of those immediately following wars' end, to be somewhat inappropriate for predicting the nature of the agricultural supply function. In reference to the future, the 1942-54 period alone may

* This will appear as Journal Paper J-2720 of the Iowa Agricultural Experiment Station, Project 1135.

[1] Wilcox and Cochrane (*Economics of American Agriculture* [Prentice-Hall, 1951], pp. 413-418) suggest that the supply function is a vertical line. Brewster and Parsons ("Can Prices Allocate Resources in Agriculture," *Jour. Farm Econ.*, Vol. 28) state that farmers do not respond to price because they are motivated by "mechanistic" rather than "economic" forces

be meaningful for predictions. The 1910-29 period represented a completely different complex of techniques, capital structure, and firm-household bonds. Because of the dearth of appropriate time-series observations and because of the complexity of the phenomena, we make no attempt to provide quantitative statements. At best, our discussion represents hypotheses about the nature of "selected variables" which enter into and affect the elasticity of the supply function. Time prohibits even a "description" of all the relevant variables.

Supply Functions for Individual Products

If the elasticity coefficient is great relevant to consumer demand, it results in wide swings in the output of particular commodities: there is a relative scarcity in some periods and a relative surplus in others. If it is too low, a relative surplus of particular products will persist over time. (We define a surplus or deficit as marginal value products which are lower or higher respectively than those which might be earned by the same resources in alternative employment opportunities, considering existing barriers to transfer of resources.) The short-run supply functions for individual farm products have relatively high elasticity under conditions of full employment. Elasticities are great enough to cause large diversions of resources between agricultural products over the span of a single year. Over the full employment periods 1920-29 and 1946-54, acreages of crops such as potatoes, flax, soybeans, sugar beets, barley, cotton, onions, pimentos, and other vegetables quite often differed between years by as much as 25-50 per cent. These are, of course, crops where the slope of the production possibility curve (or important segments of it) for individual farms and regions normally does not differ greatly from the slope of the isorevenue curve (i.e., the substitution ratio between crops differs relatively little from the "normal" price ratio). Even for major crops such as corn and wheat where substitution ratios and price ratios between products do differ considerably and a large portion of the farm plant is devoted to their production, annual changes in acreage sometimes have approached 10 per cent in full employment periods. Cattle fed and slaughter lambs fed and cattle and sheep on farms have recently changed between years by as much as 10-20 per cent. These changes in inputs of particular classes of resources (acres and animal numbers) fairly well denote changes in production planned by farmers; other classes of inputs change similarly, to the extent that they are close technical complements of land and animal units.

The interproduct transfer of resources within agriculture takes place as readily as the interproduct transfer of resources within major industrial sectors. In one sense, this transfer within agriculture takes

place with greater ease in agriculture than in industry. Most of the interproduct transfer of agricultural resources between years takes place on individual farms at one geographical location. Very little of it results from the transfer of labor and capital resources between such distinct products and locations as cotton in Alabama and oranges in California. The supply function for individual farm products is highly elastic because of these reasons:

1. The production function, particularly for annual crops, approaches an elasticity of 1.0 on individual farms. We are speaking, of course, about the crop production function characterized by a transfer of more of all resources to a particular commodity. Over a considerable acreage range on all farms, increasing land acreage in fixed proportions with its technical complements results (aside from weather fluctuations) in about a proportional increase in output of an individual crop. For example, a corn belt farmer growing twenty acres of soybeans may double his output if he pushes soybean acreage up to forty acres and at the same time doubles the input of labor and capital services; if the acreage for soybeans is diverted from corn, decreases in the output of the latter generally will be proportional to the amount of resources withdrawn. Of course, as we aggregate farms, a given percentage increase in inputs for a particular crop will result in successively smaller additions to output as the added acreage must spread to soil types less adapted to the crop. While this phenomenon cannot be looked upon as causing the elasticity of the individual farm production function to depart from unity, it does increase the slope of the supply function and causes its elasticity to decline for all farms considered together.

2. Large changes can be made in the quantity of resources used for particular products without causing important changes in the total quantity of resources employed within agriculture and causing large shifts in the geographical location of capital and labor resources.

3. The skills of labor and the services of capital resources have great adaptability between some products. For example, labor and machinery adapted to corn production are generally adapted to soybean production.

4. The production possibility curve is one with great flexibility for transfer of resources between products. On many farms, it is composed of linear (or near-linear) segments specified by the production limits of each individual resource. In Figure 1, for example, the possibility curve becomes *abcd*. If the slope of the *bc* segment falls within the range of price ratios experienced, the individual farm may readily shift product combinations back and forth between *b* and *c*. Of course, since these "between corner" segments are of different length (take on varying slopes for different farms and may even be slightly concave on

some), the aggregate supply curve for one individual product is not linear, although it has a high elasticity coefficient. (Because of uncertainty considerations, the combination of products may fall within a segment such as *bc*.)

5. Shift of resources between products often does not entail any great change in uncertainty. Resources may be on hand to produce either radishes or carrots, corn or soybeans, barley or potatoes, etc. Transfer of resources between two such products does not entail the same degree of risk as transfer of labor to a manufacturing enterprise or in adding large amounts of capital to the farm enterprise (and, consequently, in reducing the firm's equity).

The Aggregate Supply Function

The short-run supply function (i.e., one extending over a single year or two) for all farm products aggregated together presents a different picture. Either because the price flexibility of major resources parallels that for agricultural products in general or the phenomena which underly it cause the supply function to decline or to have low elasticity, output does not respond as readily to changes in factor/product price ratios. To be certain, aggregate output of farm products does respond, under conditions of full employment, to price changes. However, the aggregate output is much less sensitive to price change than is the output of individual commodities. Using 1910-29 and 1942-54 as our full employment periods, we find that gross farm production has never increased by more than 8 per cent between years; it has never decreased by more than 10 per cent. Changes this large in output result mainly from weather variations rather than from planned changes in resource inputs.[3] Changes in inputs, although slightly affected by exogenous variables such as weather, better suggest changes which farmers plan. Total inputs of agriculture increased by 4 per cent from 1919 to 1920. While most of this maximum increase was due to price, some of it also was due to above average yields. The largest decrease in inputs over a single year was 3 per cent from 1915 to 1916; some of this decline also was due to weather. Perhaps the greatest change planned between years by farmers, as measured by inputs, has never been over 2.5 per cent. A longer period of contraction was 1920-24 when both absolute and relative prices of farm products declined; total inputs decreased by a total of 5 per cent. Major expansion periods, accompanying a rise in absolute and relative price levels, were 1917-20 and 1942-49; aggregate inputs increased by totals of 8 and 9 per cent, respectively. Changes over a few years do not, of course, represent

[3] T. W. Schultz (*The Economic Organization of Agriculture* [McGraw-Hill, 1953], Chaps. 7 and 13) gives a detailed account of these quantitative changes.

a long enough time period to truly indicate the kinds of plans which are made in response to price changes. Most changes in the farm plant which affect longer run supply function rest on expectations over a period of years. Periods of full employment as long as twenty years, with factor/product ratios for agriculture drifting continuously in one direction, are probably needed before we can predict the elasticity coefficients for particular periods.

Adjustments in inputs—those facets of the supply function over which farmers do have control—have been more sensitive than examination of aggregate inputs would indicate, however. Technical innovation and relative prices have placed different premiums on resources. They have called for increases in some resource inputs and decreases in others. These changes partially cancel each other in the aggregate index of inputs. For example, total labor inputs decreased by about 10 per cent in the period 1942-49 while fertilizer increased by 74 per cent and annual inputs of building and machine services increased by 60 per cent. In the twenties period of contraction in agriculture, fertilizer and lime inputs decreased by 30 per cent in a single year from 1919 to 1920; power and machinery inputs declined by 18 per cent from 1920 to 1925, even though the "technical revolution" in agriculture was beginning to press (even in the face of declining price relatives) for use of more of these resources. We also must recognize that some sectors of agriculture have an increasing role while others have a declining role in a developing economy. Economic development occurs largely in periods of full employment. With a growth in national product and per family income, the income elasticities of demand call for a withdrawal of resources for some agricultural products and an expansion for others. These several changes within agriculture tend to cancel each other out and "obscure" the magnitude of the elasticity coefficient. While representing only small segments of agriculture, numerous farming areas can be used to show remarkable changes in product output and resource input. Negative or very low income elasticities of demand and contraction in foreign sales and other changes have provided price forces resulting in withdrawl of 40-50 per cent of the nonland resources in some areas. In other selected farming regions, growth in the national income, relatively high income elasticities of demand, and other forces giving rise to increases in relative price for particular products have resulted in large expansions in both outputs and inputs. While other forces were also at work, one need only turn to the first century and a half of American agriculture to view an extremely elastic supply function. At a lower stage of economic development and with a set of income elasticities of demand calling for increased output, agriculture

expanded in a manner which has seldom been surpassed by other industries.

Because of these many "offsetting" trends affecting resource inputs and because of the "joint variables" involved, refined prediction of supply elasticities might be obtained only through simultaneous estimation of the several structural relationships which "make up the system." Empirical predictions, with the proper degree of refinement, would undoubtedly prove the supply elasticity to be greater than a superficial examination of aggregate input and output suggests it to be. A simple plotting of aggregate farm output (or, for that matter, aggregate inputs) against agricultural price relatives, or a simple least squares prediction of the regression coefficient, probably tells us little about the elasticity of the agricultural supply function. This procedure can only provide a "mongrel relationship" which is neither the fish nor fowl of the supply function. First, there is not a supply function over a period even as short as five years, but rather a whole series of supply functions. There is a different supply function for each change in techniques, for each change in exogenous variables such as weather, for each change in the absolute or relative price of a particular resource and for each change in certainty of farmers' price expectation (both in respect to farm prices and nonfarm prices, such as industrial wage rates). Second, supply and demand functions jointly affect prices and quantity produced; where both are subject to change, an estimation of one function apart from the other may be quite meaningless. (A supply function can be estimated by least squares regression techniques only if the supply function remains constant and the demand function goes through a series of changes and price and quantities are the only variables.) Finally, the supply function for agriculture products cannot be predicted accurately apart from the demand and supply function for various categories of agricultural resources.

Aggregate supply responses may not be rapid when compared to those of individual agricultural products or to particular industrial products. However, certainly a sustained twenty-year period of full employment, with relative agricultural prices continuously moving either down or up, would give some very sizable adjustments. We are not, of course, saying that the elasticity coefficient is as great as 1.0. We are only saying that (1) in the short run it is considerably greater than zero and (2) over a period of years a succession of long-run supply curves, which consider changes in commitments of labor skills and preferences as well as in physical plant, would become operative to show agriculture as a price-responsive industry. Accordingly, we wish to summarize, first, conditions which cause short-run supply functions to

be relatively inelastic but which become greatly relaxed over longer periods and, second, phenomena which surround supply functions and cause them to appear, particularly when measured as a simple plotting of output against price relatives, to have greater slope than is actually true.

Forces Encouraging Low Elasticities in the Short Run

Supply elasticities tend to be low in the short run because of the following reasons.

1. The reservation price of agricultural labor is low for a portion of the farm population. (This phenomenon is simply one facet of flexible resource prices outlined later.) We suspect that income from agriculture relative to income from use of the same resources in other opportunities may drop by a considerable amount before many farm owners, upwards from middle age, will transfer their resources out. Not so many of their sons, however, will go into farming if incomes are relatively low. Other segments of labor also have low mobility in the short run, because of uncertainty and lack of knowledge, but would not remain in agriculture for decades under low resource returns.

2. Capital limitations place a damper on the rate at which assets are added in the short run. With a high degree of risk aversion built into their psychological make-up during depression, farmers in general may be willing to add assets only at about the rate which they can build up equities at the outset of full employment periods. Over a longer period of time, however, as the farmer's equity becomes high (as it is now), he may make large added investments if relative price ratios remain favorable and certain over a long period.

3. Because of uncertainty and capital limitations, farmers typically use so few resources that transformation ratios are considerably greater than factor/product price ratios. An increase in the price ratio brought about by a decrease in product price need not cause the amount of resources used to decline proportionately; the price ratio can increase considerably before it approaches the transformation ratio (although uncertainty may cause some contraction). As factor/product ratios decrease through a relative increase in product prices, farmers are still reluctant to drive transformation ratios lower (through the use of more resources) until they approach price ratios. However, over longer periods of favorable prices, their risk discounts may decline, allowing transformation and price ratios to be more nearly equated.

4. The production function is "more fixed" and less elastic in the short run than in the long run. The aggregate production function is limited, on the side of expansion, to a nearly-fixed plant in acreage; for single products, land can be increased in about the same proportion as all other categories of inputs. (Similarly, "space" limitations allow

particular industries to expand their plant in a "scale fashion"; production functions can have elasticities approaching 1.0.) The elasticity of production (and hence that of supply) is lower as the number of fixed resources is increased. With a fixed plant, the elasticity of the aggregate production should be less than 1.0, although it also may be composed of linear segments approaching 1.0. We doubt, however, that the aggregate production function has a "corner" separating ranges of high and low elasticity as sometimes proposed.[3] In the first century and a half of this nation, agriculture was faced with a long-run production function wherein land inputs could be increased freely and in proportion to the increased capital and labor inputs (i.e., in the sense of a "scale expansion"). We need only look back into history for indications that agricultural supply is not a variable exogenous to the economic system. No industry has responded more readily to the national economic development factors (particularly a "high" income elasticity of demand for food in a rapidly growing consumer economy). Land has, however, become largely a fixed factor (on the side of expanding the agricultural plant) in the aggregate production function. Technical innovation now acts over the long run to provide the elasticity of production formerly allowed by land. Technical innovation as it relates to the agricultural production function can be viewed in this manner: The production function is of the form $Y = f\ (X_1, X_2, X_3, X_4, \mid X_5 \ldots . X_n)$. Here, the vertical line separates resources which are variable or fixed in quantity. As the bar is moved to the left, the elasticity of the variable inputs declines; as it is moved to the right, their elasticity increases. The input of a particular resource, such as hybrid seed corn or stibestrol, is fixed at zero before the innovation. Upon innovation, the bar moves to the right of this resource (i.e., the input of the particular resource is no longer "fixed at zero" in the production function).

[3] Wilcox, "Effect of Farm Price Changes on Efficiency in Farming," *Jour. Farm Econ.*, Vol. 33, proposes this possibility on the basis of a particular fertilizer experiment. A "corner" on the production function (i.e., one segment of a marginal cost function forming a near-angle with a more vertical segment of the marginal cost curve) would allow price ratios to teeter over wide ranges across this fulcrum without specifying a different quantity of resources. However, research on fertilizer and feed with fixed production units as small as a single acre or a single animal does not show distinct corners on the production function (and hence on the marginal cost function). These "fixed plant" production functions generally show the elasticities to decline by degree rather than abruptly. Hence, the aggregate production, defined by the addition of fertilizer, feed, and their technical complements to a fixed acreage defining the agricultural plant also should have an elasticity which declines only by degrees. In fact, many farmers use resources in ranges of the production function which still have very high elasticity. While resources in the Great Plains, for example, may need to be combined nearly as "fixed technical complements" (C. Gislason, "Nature of the Aggregate Supply Function of Agricultural Products, *Jour. Farm Econ.*, Vol. 34) and may have low elasticities beyond this "sequence of tasks," the aggregate supply function need not be "sloped" accordingly. Even if every farmer has a "distinct point of production," gradations in soil productivity and adaptability would still cause the supply function, aggregated over all soils and acreage, to slope "more gently and continuously."

Hence, innovation and the increase in input of this resource (allowing it to become a variable in the production function) causes the elasticity of production for the remaining resources to increase. The longer the time period and the greater the number of innovations, the more elastic the production function becomes. (Space does not permit us to go into the details as to which resources under innovation become technical complements and "factor using" or substitutes and "factor saving.")

5. Miscellaneous forces such as the close bonds between the firm and the household, low reservation prices on particular resources and a greater degree of short-run fixed costs, also interact to give a supply elasticity which is relatively low at one point in time but which certainly increases under a long span of full employment. The forces mentioned above cause supply to be relatively inelastic in the short run but allow the elasticity to increase in the long run; they "hold output in check" over the short run of increasing price relatives, although they need not do so over longer periods. The forces mentioned below tend to encourage a given level of output even in the face of declining price relatives; but they need not support an extremely low short-run elasticity coefficient.

Variables Causing Supply Elasticity to Appear Low

As suggested by Elmer Working three decades back, any phenomena which causes demand and supply functions to change simultaneously may result in "simple empirical" observations such as those shown in Figure 2.[4] Here quantities are determined by the supply and demand pairs a and z, b and y, and c and x. If one plots the quantities against price, he obtains a "mongrel" line such as M. Using it to denote the supply functions, he would certainly conclude that it has an extremely low elasticity. However, the "true" supply function (x, y, or z) in any period has a much greater elasticity. We offer the following to explain why supply elasticity, under full employment, may be greater than sometimes predicted:

1. Flexibility in factor prices.[5] Factor prices may parallel product prices in flexibility. Supply and demand functions then move together in the fashion of Figure 2. While the supply function may be relatively elastic, the sequence of annual outputs give a "mongrel production curve" (M) with great slope. D. G. Johnson has illustrated the importance of flexible factor prices in explaining maintenance of agricultural output during depression ("The Nature of the Supply Function for Agricultural Products," *American Economic Review,* September, 1950). While applying to fewer resources, fixed factor supplies and flex-

[4] Elmer Working, "What Do Statistical Supply Functions Show?"

[5] This is the case of Marshall's stones receiving quasi-rents and can be discussed almost synonymously as inelastic factor supplies or high fixed costs.

ible factor prices also apply during relative price changes in full employment periods. Prices are relatively flexible, over short time spans, for all resource services which have their origin in agriculture. While short lags exist, prices of breeding or feeder stock and feeds generally move in the same direction as prices of livestock products. Feed and breeding or feeder stock normally make up 80 to 90 per cent of the resources used in meat production. Accordingly, with a fall in the demand schedule from *b* to *a* in Figure 2, the supply function also falls, as from *y* to *z*, because of lower prices of feed and livestock resources. In crop production, the price of land services, as denoted by share rents, also parallels crop prices in flexibility even over the short span of a
FIGURE 1
FIGURE 2

year. The reservation price of most land is near zero. Because of its limited supply in the agricultural production function, the price of its services parallels the price of its products. We have already indicated that in the short run a segment of the labor force in agriculture has low mobility and a low reservation price. Within limits, many established and older farm operators will take a lower labor return and stay on the farm rather than move to industrial employment where returns are higher. A similar situation holds true for a portion of the capital embodied in farm buildings and machinery. Over a short period of five to ten years, the major supply of building and machine services comes from stocks of these resources located on farms rather than from new stocks moved in from the machinery and lumber industries. Under declining prices, these "quasi-rent resources" are willing, because of their specialized nature, to take low returns. On the side of farm expansion (i.e., increasing price relatives), however, new machinery and building prices tend to be less flexible.[6]

[6] Numerous resources such as fertilizer and miscellaneous supplies have relatively inflexible

2. Technical change. Most technical changes, especially biological innovations, have the effect of lowering per unit costs of production; otherwise they would not be adopted. (Some techniques will be favored more in one price situation than in another; e.g., a machine technique will be favored in periods of high labor/machine service price ratios.) Hence, with declining price relative to agricultural products, output can be maintained even if the supply function is elastic. Starting from demand function c and supply function x in Figure 2 and with two successive declines in demand, the supply function may decrease to z because of technical innovation. Again, examination of changes in output will lead one to view "mongrel curve" M, and suppose the supply function has an elasticity of nearly zero. Actually, the elasticity may be much greater, as is suggested by curves x, y, and z.

3. Capital accumulation and redistribution of assets. Full employment periods tend to bring about some redistribution of agricultural resources, particularly land. Job opportunities and wage rates which are higher than "reservation returns in agriculture" pull the more mobile portion of the labor force out of agriculture. Some farms are released for rental or purchase by others. At the same time, favorable farm profits give some remaining operators funds to add to their holdings. Changes in farm size apparently have been, aside from retention of part-time and nominal units, quite large in many agricultural areas. In overcoming historic, institutional, and other barriers, units which are more efficient in use of machinery have emerged most rapidly in full employment periods.[7] Because of the machine cost economies associated particularly with crops, cost functions have tended downward. With declining costs, the pattern of Figure 2 may again be traced out to suggest "mongrel curve" M.

This paper has provided hypotheses about major variables affecting the elasticity of the supply function. Time has prevented discussion of other variables. Unfortunately, the paper has the limitations of many other journal articles. It is mainly a "set of literary hypotheses." Urgently needed is an empirical study which predicts the many coefficients in the set of structural relationships and which are necessary for meaningful statements about supply elasticity.

---

prices, as compared to farm products. Whether or not the price is flexible makes little difference for a resource which is a technical complement to another resource which does have a flexible price and makes up a small portion of total inputs. For example, inflexibility in the price of livestock minerals, small tools, and similar items has little bearing on the use of such resources.

[7] Although there are, in the terms of Gislason ("The Nature of the Aggregate Supply Function of Agricultural Products, *Jour. Farm Econ.*, Vol. 34), still "a sequence of tasks directly related to cultural practices to be done," these can be accomplished as well by the consolidating farm as by the previous small owner.

A MODEST PROPOSAL FOR SURPLUS DISPOSAL

By Martin Bronfenbrenner
University of Wisconsin

The philosopher, T. V. Smith, when discussing matters outside his professional ken, takes care to speak "as an ignorant man and a philosopher." I do not yield to T. V. Smith in ignorance, but I am not a philosopher. The general economist, however, stands to the expert in specialisms like agricultural economics in somewhat the same position as does the philosopher to the social scientist. So perhaps I may be pardoned for appearing before you "as an ignorant man and a general economist."

Any ideas of mine on agricultural surplus disposal must be modest because of my ignorance. These particular ideas will be for another reason as well: they are largely unoriginal. They are based not on things unknown but on things forgot—and only partially forgot at that. They are largely a refurbishing of the McNary-Haugenism of the twenties, with a dash of econometrics borrowed from the forward pricers and a dash of Keynes borrowed from the Keynesians. The sum total, I have been told, is not very different from the practices now in use in surplus disposal for perishable commodities like butter.

A relapse into McNary-Haugenism is defensible. This philosophy was too radical and revolutionary for the Era of Wonderful Nonsense in which it originated, the nonsense then including federal budgets balanced at about 3 billion dollars. It has become conservative and old-hat in the present Era of Wonderful Nonsense, which includes support of everyone's prices and wages and letting inflation take the hindmost. Now Nonsense Can Be Wonderful and Life Can Be Beautiful, without excluding occasional deviations into sense, or into death.

Preconceptions of an Ignorant Man. An easy first step in solving the surplus disposal problem would be stopping all future surplus accumulation. This could be done, as we all know, by free markets, by forward pricing (in periods of high employment), by stringent acreage and output controls, or by crop destruction, etc. But the political strength of organized agriculture, the log-rolling skill of its spokesmen, the positive appeal of the parity idea, the negative appeals of subsidies, output limitation, and "killing little pigs" combine to preclude elimination of surpluses through lower prices or reduced output. Therefore I take for granted that we shall have with us a problem of disposing of increments to surpluses, as well as of existing or holdover surpluses,

substantially more than half the time for most of the major storable farm crops at going prices.

By a surplus I mean explicitly an amount larger than required as a disaster reserve for the United States or as the American share in a disaster reserve for the world at large. I mean, also, an amount larger than can be distributed feasibly in school lunches or poor relief anywhere in the world without distorting the normal markets for the goods we are considering. I recognize, also, sufficient limitations on farm bloc power to rule out as not only dictatorial but impracticable all suggestions to eliminate food surpluses by setting up compulsory "adequate" diets as liens on the disposable incomes of nonfarmers. In short, I am trying to render the surplus disposal problem nearly as difficult in my model as it is in real life rather than defining important aspects of the problem out of existence at the start.

The subject of our panel relates particularly to the international aspects of surplus disposal. Here again it would be easy to assume as the goal of our international economic relations a set of free-competition and free-trade policies which would simplify the issues tremendously. Free competition and free trade would restrict our surplus accumulations and decumulations within the dimensions of disaster insurance funds. They would outlaw as monopolistic any accumulations and disposals, at least by individual countries, intended primarily to influence either world or domestic prices. They would equate the domestic prices of all our agricultural imports and exports with world prices, adjusted for transport costs. I cannot disagree with Professor Johnson's position, for example,[1] that such are the logical consequences of free trade as applied to agriculture. But once again, I propose to assume instead that the farm bloc, having not only tasted blood but gorged upon it for the better part of a generation, will be able to veto many of these corollaries of free trade. Instead of free trade, then, I am asking you to assume with me that our international economic policy be limited to the less exciting goal of multilateralism—meaning effective competition by all exporting countries in the markets of all importing countries but normally not effective competition between foreigners and domestic interests. In this connection, the term country should be defined broadly enough to include customs unions like Benelux, temporary customs-union arrangements like the US-Philippine Trade Pact, and preferential areas like the British Commonwealth and French Union. But on one other point I must ask your indulgence for evading a problem which may be more significant than I

[1] D. Gale Johnson, *Trade and Agriculture, A Study of Inconsistent Policies* (Wiley, 1950), Chaps. 1, 2, 11; "Agricultural Price Policy and International Trade" (Princeton: *Essays in International Finance*, 1954), pp. 8-11.

believe it is. I wish to speak mainly in terms of a single abstract "agricultural product" and ignore special problems of individual crops and of complementary or competitive relations between them. I am thinking of this abstract agricultural product as a storable item, with low transport costs relative to its normal value. It is normally an American export item, which may, however, be imported if the American price is above the world price. It is a raw material for other products, agricultural or industrial, in which Americans compete with foreigners in both domestic and foreign markets. Wheat, corn, and cotton are three important feet which this shoe seems to fit quite well. I hope we do not lose too much by neglecting other feet of the agricultural centipede, which the shoe fits rather badly.

The Proposal. The leading features of the plan I wish to lay before you can be outlined under a few main heads.

Instead of supporting domestic prices by no-recourse loans, let a public corporation like the present Commodity Credit Corporation or the Hoover Farm Board purchase agricultural surpluses for cash at support prices. (I suppose that there will be such support prices, whether based on "parity" or not, and whether rigid or flexible in character. Among these various methods of supporting farm prices, I refrain deliberately from any choice. The surplus disposal problem is difficult enough "for an ignorant man and a general economist" without throwing in the entire "farm problem.") Title will rest clearly in this public corporation—let us call it Federal Agricultural Surplus Corporation or FASC, if we can stomach the fascist implications of the initials. FASC will then have full authority and full responsibility for disposal of surpluses.

At the end of every crop year, let the FASC set up a monthly schedule for the next twelve months of the sales to be made on the world market at world prices, whatever these may be. Let this international sales schedule be public knowledge. Let the FASC actually make these sales, either directly or through private exporters. (If sales are made to private exporters, they should be made by competitive biddings; i.e., at whatever prices exporters can afford at current and prospective world market prices. The roundabout procedure of selling to exporters at domestic prices and subsidizing their losses when they sell at world prices should be replaced by surveillance to prevent diversion of export purchases back to the domestic market. If the United States adheres to an international agreement governing the commodity, deliveries of American export quotas to the international commodity authority should not be included in the international sales schedule.) In years of disaster or the abatement of disaster at home and abroad, the FASC must of course be permitted to revise its international sales schedule

downward or upward for the remainder of the crop year, but only after the maximum practicable amount of public notice.

The aggregate sales during any normal crop year should exceed the increment to surplus in the preceding crop year, and therefore reduce the accumulated surplus on hand. The FASC should not, however, wreck the world market (as the Farm Board did in 1931-32) by dumping its entire accumulation at one fell swoop. It need never lower its normal holdings below a reasonable disaster reserve or "ever normal granary," as estimated by competent commodity specialists with a minimum of political interference. This reserve, of course, should not be held idle when disaster actually strikes, like gold reserves under some versions of the gold standard. They should be drawn upon to meet the drought, flood, war, or other emergency and replenished later.

Some arbitrary figures may illustrate how this scheme might work, how far the FASC can be guided by fixed rules, and how much discretion it must apparently be awarded by the nature of the problem. Let the accumulated surplus prior to the initial year of this plan (year 1) be 10 million units (bushels), including 2 million bushels from the crop of the year immediately prior (year 0). Let the safe disaster reserve be estimated (discretionarily) at 5 million bushels. Then the amount to be sold on world markets during year 1 might be from 2 to 7 million bushels, distributed by months according to the ordinary seasonal pattern of world demand. Suppose the figure chosen is 3 million bushels. This would leave the surplus at the beginning of the next year (year 2) at 7 million bushels plus the increment of surplus from crop year 1. If this increment of surplus exceeded 2 million bushels, annual sales by FASC in year 2 would presumably exceed the 3 million bushels of year 1; if the increment fell short of 2 million bushels, annual sales would presumably be less than 3 million bushels. But these are discretionary decisions, subject only to the general rule that sales in each normal crop year should exceed the increment to surplus from the last crop year whenever the total surplus exceeds the disaster reserve. (This simple illustration presumes a static situation, in which the disaster reserve remains constant over time. In actual practice, there will be increases and decreases in the reserve, depending on such factors as increasing population, changing foreign production, development of substitutes, improvement of transportation, revised probability assumptions, etc.) When the surplus falls, in year *t*, to 5 million bushels plus the increment of year *t*-1, the program of year *t* would be limited to disposal of the last year's surplus.

If, through any reason (disaster or miscalculation), the surplus at the beginning of year *t* should fall short of 5 million bushels plus the in-

crement from the previous year's crop, part or all of that increment would be retained unsold.

Should a disaster (crop failure, flood, drought, war, etc.) occur or be in prospect, the disaster reserves would of course be mobilized and not held idle. At the same time, at FASC discretion, the international sales schedule for the remainder of the crop year might be reduced or canceled. FASC should also be given discretion to increase or reinstate an international sales schedule when a shortage ends during a crop year or when a threatened crisis fails to materialize.

The heart of this proposal lies in the public announcement each August or September (say) of the FASC's monthly international sales schedule for the next year. If the disaster reserve has been dangerously depleted in prior years, there may be a purchase instead of a sales schedule. This procedure allows for dribbling, but not in most years for dumping,[2] the American surplus upon the world market at prices below American domestic ones. It withdraws the looming threat that the United States may wreck the world market entirely by disposing of its entire accumulation. Normally it exerts a constant downward pressure on world prices. This should not be belittled if world demand is inelastic, but on the other hand, when we consider the inelasticity of American domestic demand, this downward pressure may be little greater than it would have been in a completely free American market with the domestic price lowered to the world level. The added depressive element may also be offset in part by the added element of certainty implied by the scheduling of sales by the FASC. This certainty is itself not complete, covering only a year at best and subject at worst to drastic and sometimes destabilizing revisions[3] of the international sales schedule, in response to the rumors, presences, and abatements of droughts, floods, locusts, and wars.

Financing. Buying at high domestic prices and selling at lower world prices, the FASC is doomed to financial losses in normal years, which

[2] Our distinction between dribbling and dumping loses much of its validity in years of unusually large surplus accumulation. In the case of wheat, for example, the Commodity Credit Corporation's holdings amounted on June 1, 1954, to 878.6 million bushels as against 514.4 million on the preceding July 1. Disposal in the single year of 364.2 million bushels, or 70.8 per cent of the previous total, is hardly a dribble

[3] As an example of destabilization, assume a failure of the Indian wheat crop, met in part by depletion of the American disaster reserve. The depletion is accompanied by a reduction of the American international sales schedule for the remainder of the crop year. The world wheat price, raised by the short crop in India, may be raised further by the reduction of the American international sales schedule. (The lowering of the American disaster reserve will be an offset, but usually not a complete one.) A similar argument applies on the downward side of the market when a crisis situation is concluded or avoided. Here the combination of American disaster-reserve and international-sales-schedule changes may lower world prices by more than they would have fallen with no revision of American policies.

will probably exceed its expected gains from operations with the disaster reserve. Under the present system, losses can be concealed for long periods by carrying surplus stocks, or nonrecourse loans based on them, upon the books of public corporations as assets valued at purchase prices. (During the political campaign of 1954, the total cost of the existing farm price support program since 1933 was often stated at less than 1.5 billion dollars, at a time when the Commodity Credit Corporation was holding over 6.1 billion of such questionable "assets.") The losses would be revealed almost immediately by any plan requiring, as this one does, drawing down of surpluses above a disaster reserve. (The disclosure feature is, in my judgment, a point in this plan's favor; many will doubtless judge otherwise.) At any rate, the problem of how the FASC deficit will be financed arises sooner and more continuously under this plan than under the existing system.

Prior to the Keynesian revolution of 1936, it was taken for granted that such deficits would be financed completely by farmers, or if not by farmers, by the processors of agricultural products.[4] This would avoid drain on the general funds of the federal government and conform to the period's concept of sound finance; namely, a balanced or slightly overbalanced budget of minimum size. A number of proposals satisfying this condition were made during the period 1921-32.[5] Of the few proposals which I have read, the most impressive appears to be the McNary-Haugen "equalization fee." Under this plan, federal marketing losses on each commodity would be financed by a specific levy[6] on each acre of land sown to that commodity by a farmer participating in the plan. The levy, which we may call an equalization fee, would be assessed whether the crop was marketed or used on the grower's farm, except that no farmer should be required to pay more in equalization fees than the difference between domestic and world prices on the quantity which he actually sells.

Participation in the plan and payment of equalization fees should both be voluntary. Nonparticipants, however, should not be permitted to sell on the domestic market at the supported prices. They should be restricted to foreign sales or to the use of their output on their own

[4] A typical statement of the underlying ethics is from George N. Peek and Hugh S. Johnson, *Equality for Agriculture* (Moline, Ill.: Moline Plow Co., 1922), p. 15, reproduced by Murray R. Benedict, *Farm Policies of the United States, 1790-1950* (Twentieth Century Fund, 1953), p. 210: ". . . agriculture ought not to produce a surplus which cannot be sold above cost of production, and if it does so produce it must stand the loss. Every farmer who produces contributes to that loss and ought to stand his share of it."

[5] Benedict, *op. cit.*, Chaps. 10-11. In addition to the equalization fee plan discussed immediately below, the "export debenture" and "domestic allotment" plans achieved wider support during this period than did any other proposals dealing at all seriously with financing problems.

[6] In conformity with some recent Farmers Union proposals, progression might be introduced into the levy as a measure to encourage family over corporate farming.

farms. Such a restriction as this was a feature of the domestic allotment plans of Professor Black and others during the late twenties.[7]

The equalization fee mechanism has a definite political advantage over financing from the general fund. It reduces somewhat the farmer's stake in high domestic prices, which he must now pay himself in part. It therefore reduces the conflict between the farmer on the one hand and the consumer or taxpayer on the other. This mechanism has also a corollary economic advantage over financing from the general fund in that it reduces the farmer's incentive to allocate his resources to the "wrong" crops,[8] whose prices are being supported above the level justified by the world demand for them. (This text has been criticized for failure to consider the export debenture plan, which would accomplish the same purposes as the equalization fee by a reverse mechanism. Under the export debenture system, the farmer receives the export or world price plus certificates whose value varies with the domestic price and the losses of the price supporting agency. The export debenture plan achieves greater simplicity than the equalization fee but is more difficult to adjust to modern fiscal insights, as indicated below. It also forces farmers to become speculators against their will and inconsistently with their abilities if they must sell certificates for cash before the value of the certificates is determined.)

There are also sound economic arguments in favor of general-fund financing of any FASC deficit. Modern fiscal policy teaches that a budget deficit may be a desirable means of increasing total expenditure when the national income is not keeping pace with productive capacity. General-fund financing of an FASC deficit would increase the flow of income at such times and should not be renounced in advance by exclusive reliance upon equalization fees or other schemes of self-financing. And even in normally prosperous times, a general-fund contribution to the normal FASC deficit may be useful to induce participation by small farmers who market relatively little of their produce.

The advantages of the equalization fee can be combined with the insights of modern fiscal policy, at the cost of some complications of administrative procedure. Each year's FASC deficit may be financed in the following year, partially from the general fund and partially by the

[7] John D. Black, *Agricultural Reform in the United States* (McGraw-Hill, 1929), Chap. 10. Also W. J. Spillman, *Balancing the Farm Output* (New York: Orange Judd, 1927), *passim*. Cited by Benedict, *op. cit.*, p. 267.

[8] Doubt has arisen regarding the quantitative importance of misallocation of resources between crops under the existing programs, once these resources have been committed to some form of agricultural activity. It is difficult to find farm products which are being "underproduced" because of the overproduction of those whose prices are being supported. Cf. J. K. Galbraith, "Economic Preconceptions and the Farm Policy," *Amer. Econ. Rev.*, March, 1954, pp. 46-48. Professor Heady's paper represents a rebuttal to these skeptical doubts, valid (in my opinion) for sufficiently long periods, less valid for the short term.

proceeds of commodity equalization fees. The proportion between the two parts, however, should vary with the business cycle in a sliding scale. The government should foot most or all of the bill when conditions are generally depressed; the farmer should foot most or all of the bill when inflation threatens the general economy. Farm income from price supported commodities may be expected to correlate with the national income more closely than farm income in general. It will be most unusual to find equalization fees major burdens on, say, wheat farmers in inflationary periods, even though income from wheat might

FINANCING THE FASC DEFICIT

If GNP in Year t Exceeds GNP in Year $t-1$ by	The FASC Deficit of Year $t-1$ Should Be Financed in Year t by	
	Equalization Fee	General Fund
Less than 0%	0%	100%
0–2	20	80
2–4	40	60
4–6	60	40
6–8	80	20
More than 8	100	0

have moved quite inconsistently with the national income in the absence of support for wheat prices. The variable equalization fee and the variable government contribution would then operate as a small "built-in stabilizer" for the control of economic oscillations.

A possible basis for division of the deficit is indicated in the table. It depends upon the year-to-year rate of growth of the gross national product in current prices. Percentages above and below the long-term upward trend of national income or product would be more desirable, given a substantial measure of agreement upon the trend line itself. Variability is provided, but changes are to be made according to rules with little or no administrative discretion.

These figures are included purely as illustrations. Experts in agricultural finance may devise other schedules using the same principles and arriving at more equitable results.

In some years FASC operations will show surpluses. These will be years of scarcity in which disaster reserves are being liquidated at high prices. The surpluses should be held in special funds against subsequent deficits, in the manner of the Social Security Trust Funds. Accounts for each crop should be separated insofar as possible, so that the equalization fees paid on each crop will contribute to FASC deficits in the purchase and sale of that crop. Suppose that, in year t-1, FASC operations show a profit in cotton and a loss in wheat. Wheat farmers should then pay equalization fees, in year t, even though the over-all

FASC operations of year t-1 show a surplus, and cotton farmers should pay none even though the over-all operations of the FASC show a deficit.

Tariffs and Quotas. Free trade in agricultural products and in products largely manufactured from them is impractical so long as government policy holds the domestic and the world prices of agricultural products apart. It would be pointless, for example, to permit free imports of corn and pork while holding the domestic price of corn above the world price. The result of free trade in corn would be that the FASC would buy the entire American corn crop, while foreign corn would take over the entire American market for reasons completely unrelated to comparative advantage, relative factor endowments, or other determinants of the normal flow of free international trade. If foreign corn were excluded from the American market, free trade in pork products would drive the American hog raiser out of business because of higher feed costs, again without justification in the theory of international trade. Professor Galbraith (*op. cit.*, page 49) puts the same conclusion in reverse: after domestic prices have been raised, departure from free trade "restricts imports that have first been made artificially attractive."

This much is elementary. It is equally elementary that no fixed tariff rates, either specific or ad valorem, can serve as offsets for the differential between domestic and international prices when the differential itself is a variable. My suggestion, therefore, is that fixed tariff rates both specific and ad valorem, on both agricultural products themselves and their principal products, be replaced by schedules of flexible rates. The flexible rates should vary automatically as often as is practicable—every month, quarter, or year—with the differentials between the domestic and the world prices of agricultural products. The differentials should be computed as absolute amounts in connection with specific duties, and as percentages in connection with ad valorem duties.

This sliding-scale system is preferable to the alternative system of supplementing tariffs with import quotas and with tariff quotas. This alternative system, while more arbitrary, is simpler and is more favored in present American practice. A sliding-scale duty system has the advantage, however, of leaving the American market attainable to foreigners who lower their production costs by increased efficiency not connected with the differential between American and world prices, while the quota system makes no subtle distinctions among the causes of increased foreign imports. Furthermore, the sliding-scale duty system has the advantage of reducing discrimination between individual importers and exporters. The windfall rewards for getting particular consignments in under quotas will be reduced, and also the windfall

losses for getting them in late. A certain amount of discrimination, however, will remain as necessary consequence of periodical rate changes

International Agreements. We have been speaking of a two-price system, in which there are only world and domestic prices. This is an oversimplification—sometimes a dangerous one. If there is an international commodity agreement covering our agricultural product, exporting and importing countries will meet annual quotas and an international agency will accumulate disaster reserves. Export and import quotas will be met at an agreement price which, being fixed for a reasonably long period, will normally differ somewhat from the actual deal. The "agreement price" is itself usually double. There is a buying price for export quotas and a selling price for import quotas. The selling price is normally somewhat higher than the buying price. The administrative and storage expenses under the international agreement are wholly or partially paid out of the differential between the two prices.

In normal years, we are safe in supposing an agreement price lying somewhere between the high American domestic price and the low unregulated world price. In scarcity years, the agreement price will be the lowest of the three. In considering whether the United States should participate in such an agreement, attention should probably be concentrated upon the normal or surplus years. If circumstances are as we have supposed them, the agreement will then offer an outlet for part of the American surplus on terms more favorable than the world market. On the other hand, the United States will be required to finance a share of the administrative expenses and operating losses of the agreement. I can see no better way to determine American policy toward the agreement than the cold-blooded one: to weigh the probable gain in lower FASC losses against the probable loss in administrative contributions, to join if the former exceeds the latter and to abstain in the reverse event. In the interests of international comity, we should in no case join in years of export surplus and then withdraw or welsh on our delivery quotas when there is a shortage and the world price rises above the agreement one. Such double-dealing is currently ascribed (1954) to some importing countries (e.g., France), which joined the International Wheat Agreement when world wheat prices were high and refuse to accept their quotas when the Agreement price exceeds the free world price.

Bilateral Arrangements.[9] Pressure to dispose of farm surpluses by

[9] The writer has received substantial aid in preparing this section, particularly with regard to recent legislation, from a mimeographed paper by Professor J. S. Hillman which formed the basis of his essay, "Impact and Problems in Administration of Export Programs," *Jour. Farm Econ.*, February, 1955, pp. 96-109.

bilateral arrangements with importing countries is at least as old as the early twenties. For example, Senator George W. Norris introduced a bill into the 67th Congress (1921-23) establishing a 100 million dollar government corporation to buy farm products for cash in the United States, sell them abroad for foreign bonds, and then market the bonds in the United States. (Benedict, *op. cit.*, page 207.) A wide variety of such arrangements has been attempted. Unlike Nazi Germany and Soviet Russia, the United States has abstained thus far from large-scale direct barter agreements in specific commodities, but postwar legislation has been edging closer to the Nazi-Soviet model. During the Hoover administration, however, the Federal Farm Board not only sold wheat (to Germany and China) below world prices, but also bartered 25 million bushels for Brazilian coffee (*ibid.*, page 334). (This occurred prior to the Nazi elevation to power in Germany!)

The American bilateral arrangements have been of three general types:

1. "Tied loans" by the Export-Import Bank and other institutions, to finance purchases of American agricultural products (particularly cotton) for dollars at domestic prices. These have been part and parcel of American trade policy since the Export-Import Bank was founded in 1934. Even prior to the founding of the Export-Import Bank, the Reconstruction Finance Corporation made a tied cotton loan to the Soviet Union (*ibid.*). Foreign aid legislation since the first Economic Co-operation Act of 1948 has arrived at the same tying principle by indirection, the key provision being that no funds be used to finance purchase from third countries of agricultural products in surplus in the United States.

2. Earmarking of portions of American economic grants-in-aid, first to Europe and later to underdeveloped countries elsewhere, for purchase of surplus American farm commodities for dollars. Until 1953, purchases were at the domestic American price or the Commodity Credit Corportion acquisition price, whichever was the lower, but Section 550 of the Mutual Security Act of 1953 permitted sales at lower prices under bilateral agreements with the approval of the Department of Agriculture.

3. Sales of surplus American agricultural commodities for foreign currencies, which are then devoted to off-shore procurement of military goods and for purchase of strategic materials. The goods are ostensibly sold at domestic price equivalents in the absence of specific agreements authorizing lower prices, but the foreign-currency equivalents are often computed at unrealistic "official" exchange rates in such wise that a substantial discount enters the transaction in fact even when it is concealed on the surface. The most recent legislation on foreign surplus disposal, the Agricultural Trade Development and Assistance Act of

1954 (Public Law 480, 83rd Congress; approved July 10, 1954; 68 U. S. Stat. 454-59), is of this type.

Pedantically speaking, products sold abroad under these schemes include more than actual surpluses in public hands. They include, also, stocks which would have entered into surplus if not sold abroad. They include commodities like dried fruit, for which no price support or surplus accumulation program is in effect. It seems nevertheless permissible as a simplification to include all these categories as elements of surplus. Even in the most questionable category—products not under the price support umbrella—inclusion in bilateral arrangements seems to have been intended as a substitute for more direct government support of domestic prices.

Under all these programs, the enabling legislation includes a proviso against interference with normal American exports, with world market prices, and with the marketing of the agricultural produce of "friendly nations," including presumably the importing countries themselves. A friendly nation is defined in Section 107 of the Agricultural Trade Development and Assistance Act of 1954 as "any country other than (1) the U.S.S.R., or (2) any nation or area dominated or controlled by the foreign government or foreign organizations controlling the world Communist movement." If these provisos were never ambiguous and always taken seriously, they would limit the scope of these programs almost entirely to short-term emergency aids. Such, if I understand his essay correctly, is one of Hillman's criticisms of these programs: except under emergency conditions, they are so hedged in by these limitations as to be of insignificant quantitative importance. Hillman (*op. cit.*, Table 2) presents Department of Agriculture figures indicating a total of 245.1 million dollars of authorizations under Section 550 of the Mutual Security Act of 1953 for thirteen countries through July 8, 1954. During the same period approximately, total surplus holdings of the Commodity Credit Corporation rose by 2,633.0 millions, or ten times as much!

On the other hand, these limiting provisos are ambiguous and may in fact be disregarded at administrative discretion. They have been disregarded in the past, particularly as they protect foreign and not American agriculture. They have been disregarded either through ignorance of administrators or through political pressures upon them. It is safe to assume occasional disregard in the future as well. If the protective provisos are disregarded, more substantial surpluses may move under these programs at the price of increased international ill will and possible international retaliation.

The present (1954-55) rice situation in Asia illustrates the ambiguity involved and the leeway for administrative discretion. Since 1945,

American rice exports have risen from a prewar average of 80 thousand tons a year to 800 thousand tons in 1953. Much of the increase went for relief purposes; Japan was the principal recipient under bilateral arrangements. The program did not prevent a steady rise in world rice prices. The three leading prewar exporters had been Burma, Thailand, and Indo-China. For seven years following 1945, exports from both Burma and Indo-China were hampered by war damage and civil conflict. Beginning in 1953, however, Burman recovery turned rice prices downward. Continued pre-emption of the Japanese import market by the United States through 1955 may mean not only a break in world rice prices but also years of delay in the development projects of Burma and Thailand, which are financed largely by profits on rice exports, and a shift of Burman "neutralism" in an anti-American direction. At the same time, rice is one of the six "basic" commodities of American farm price policy. About 1.4 million bushels are expected to pass into surplus from the record 1954 crop. (Cf. "Too Much Rice in Hungry Asia," *Business Week*, November 6, 1954, pages 142-145.) Domestic political pressure has been strong for requiring Japan to import primarily from American surplus stocks as a condition for receiving American economic aid, since such action appears a passive matter of maintaining an American rice export market against Burman competition rather than as active matter of expanding American exports to areas traditionally served by Burma. Burma has previously never been an important source of rice for Japan except when the Japanese or Korean crops failed. In the decade following 1930, Japan obtained nearly two-thirds of her necessary imports from Korea, and approximately one-third from Formosa. (Cf. Jerome B. Cohen, *Japan's Economy in War and Reconstruction* [University of Minnesota Press, 1948], pages 368 f.)

Since the above paragraph was written, a draft Japanese-American aid treaty has been released to the press, according to which American pre-emption of the Japanese grain import market will be concentrated in rice substitutes (wheat and barley) rather than rice itself. This solution will dispose of American wheat and barley rather than rice surpluses. It will avoid economic conflict with Burma but will be resented by producers of rice substitutes (chiefly sweet potatoes) within Japan's domestic economy.

It is conventional to denounce bilateral arrangements in the interests of multilateral international trade. I follow this convention to the extent of omitting bilateral arrangements from the general surplus disposal program outlined here. There are, however, two sets of circumstances under which bilateral arrangements seem to have some legitimate place in a surplus-disposal program, however multilateral may be

our final or even our immediate ends. These circumstances can be spelled out explicity as "reservations."

1. A "distress" reservation. We agree on the permissibility of gratuitous gifts of agricultural surpluses to meet major, acute emergencies abroad. If the greater includes the less, it seems equally permissible to sell the same agricultural products at cut rates, to sell them for overvalued currencies, or to barter them for overvalued exports of the distressed countries, if the emergencies are less acute than those calling for international charity. But such sales should be permitted only with the agreement of other major exporters of the agricultural products concerned. In the Japanese rice deficit, no bilateral arrangement between the United States and Japan should go into effect without the approval of Burma, Thailand, Viet-Nam, and Cambodia, the principal rice exporters of the Far East.

2. An "inconvertibility" reservation, which can be illustrated from the recent history of Japanese cotton imports. Suppose American cotton cheaper than Pakistan cotton in Japan at existing official exchange rates, but suppose the Japanese pressured by sterling bloc regulations to purchase the more expensive Pakistan product. (Japanese sterling balances are freely available to purchase cotton from Pakistan, a sterling bloc member, but not to purchase cotton from America, which is not a member.) A dollar loan to Japan, even if tied to purchase of American cotton, is then less an interference with multilateral trade than it is a restoration of multilateral trade in retaliation against an interference by the sterling bloc.

Summary. While a candidate for his first presidential term in 1932, Franklin D. Roosevelt delivered his major agricultural policy address at Topeka, Kansas. He set forth in this address the requisites of an ideal farm program—which were not always to be met during his own administration. But the ideal is stated clearly, and we can use it as a kind of yardstick against which to measure the proposal just outlined.[10]

Roosevelt said that the ideal plan should provide for the American farmer the benefit of the domestic market without causing him to increase production. This proposal comes close to meeting this specification with regard to export commodities during periods of prosperity, when equalization fees are high. It falls short during depressed periods, when the fees will usually be lower and FASC losses met out of the general fund. While not positively encouraging farmers to leave the farm when there are ample opportunities outside, it does not encourage

[10] Franklin D. Roosevelt, *Public Papers and Addresses* (Random House, 1938), Vol. I, pp. 693-711. Cited by Benedict (*op. cit.*, p. 273), who suggests that Roosevelt may have framed his ideal with special attention to the domestic allotment plan.

them to stay there; it encourages them to stay where they are when unemployment is reducing alternative opportunities in industry.

Roosevelt said that the ideal plan should be self-financing. To current ways of thinking, self-financing is less obviously a virtue than it seemed in 1932. Our proposal, however, seems self-financing when it is desirable on fiscal grounds for it to be self-financing. It is not self-financing in periods when fiscal theory suggests monetary expansion through federal deficits.

Roosevelt said that the ideal plan should not use any mechanism that would cause retaliation on grounds of dumping. This proposal does involve the name of dumping, as does any other proposal to hold the domestic above the world price. On the other hand, it avoids one of the most undesirable features of dumping; namely, erratic and unforcecastable onslaughts upon the world price level. Also, in view of the inelastic domestic demand for most farm products, the depressive effect of this plan upon world prices seems little more than would result from American exports in a free market with no protection for the domestic American price. As an additional feature, the plan encourages American participation in international agreements including both exporting and importing countries, and designed to insure both groups against the consequences of price fluctuations. Roosevelt said that the ideal plan should be voluntary. This plan is voluntary, at least in form, which may have been all Roosevelt had in mind.

Roosevelt also said that the ideal plan should make use of existing agencies and should operate on a co-operative basis. The restriction to existing agencies beats strangely upon ears attuned to Roosevelt's subsequent alphabetical extravaganzas, but I find it not unreasonable; my proposed FASC is little more than the existing CCC (and many a predecessor) reinitialled. "Operation on a co-operative basis" means that operating farmers should have a leading voice in the administration of the plan. Participation by farmers is good politics; it is apparently as easy to erect a window-dressing of dirt and dirt farmers for one plan as for another.

I cannot claim an "A" rating in agricultural economics for these random ideas by the rigorous Roosevelt standards of 1932, even ruling out such standards as I cannot accept. But I think I can hope for a "B," or at the very least a "graduate B minus." Even that would not be too bad, "for an ignorant man and a general economist."

DISCUSSION

D. GALE JOHNSON: In his "modest proposal," Bronfenbrenner has specified two conditions for the appropriate behavior of the United States if and when it dumps or dribbles its agricultural surpluses. One condition is that we should never sneak up on our adversaries, i.e., competing producers, but should let them know in advance that we are going to clobber them, what we are going to clobber them with, and how hard we are going to clobber them. The other condition is that Uncle Sam should play as small a role as possible in financing the dumping; US farmers should, under conditions of expanding GNP, pay part or all of the cost of the dribbles. In other words, in this competitive battle for export markets, the US should not allow her farmers to bribe the referee unless it is necessary to do so. Thus in this new set of Marquis of Queensbury rules for the dumping arena, it is not cricket to sneak up behind one's opponent and bash his head in without letting him know you are going to do it nor should the fantastically large resources of the US Treasury be used to make it certain that there cannot be a fair battle between US farmers and those of competing nations.

In my opinion, if we are to continue our foreign surplus disposal operations, there is no question that a set of rules or guides to appropriate conduct should be followed. On the whole—and not arguing that there have been no exceptions—it would appear that the administrators of our surplus disposal programs since the end of World War II have followed a code of behavior that has tended to minimize the undesirable side effects of our dumping operations. It has generally been fairly well known what our export price will be for wheat—the major commodity subject to export subsidization. And administrators have shown considerable restraint in using the omnibus authorizations such as contained in Section 550 of the Mutual Security Act or the more recent Agricultural Trade Development and Assistance Act of 1954.

Despite the past restraint and general good sense that has been shown in the administration of export disposal programs, I agree with Bronfenbrenner that a procedure should be adopted which minimizes the degree of uncertainty attendant upon such operations.

As a transition to my brief comments on Heady's paper, let me twit Bronfenbrenner for accepting a Galbraith economic preconception which turns out to be a misconception. Our "ignorant man and general economist" seems to accept the idea that relative prices have little or no effect upon the allocation of resources in agriculture since it is difficult to find farm products which are being "underproduced" because of the "overproduction" of those whose prices are being supported. What, pray tell, is a sensible definition of underproduction? Unless the government intervenes, in a competitive industry the amount produced or supplied is approximately equal to the amount demanded at some price. The price of beef cattle is not supported nor controlled by government action. How could one detect whether beef is being underpro-

duced? Since one cannot define underproduction in any sensible manner, it is perhaps not surprising that it is difficult to find it. After all, who can find the black cat in the dark room when the black cat isn't there anyway?

What is important here is the elasticity of the supply of agricultural output as a whole and of the various individual farm products. The implication of Galbraith's preconception is that all such elasticities are zero or so near to zero that the difference is unimportant. Heady would not accept such a view and the reasons he gives are convincing to me, which is hardly surprising since I was already convinced.

Heady's paper does much, in my opinion, to dispel the notion that agricultural output is so inflexible—the elasticity of supply so low—that disaster would strike agriculture if an attempt were made to relate agricultural prices to market demand and supply relationships, such as is encouraged in a forward price proposal or even actual free markets. But it is pertinent to point out that a low price elasticity of supply, either for one or all agricultural products, is not necessarily a calamity so great as to justify any measure designed to stabilize farm income. The responsiveness of farm prices—and thus of farm income assuming a low price elasticity of supply—to changes in the level of national economic activity is a function jointly of price and income elasticities of demand and price elasticity of supply. Thus the elasticity of farm prices with respect to changes in national income is equal (assuming constant elasticity functions) to the income elasticity of demand divided by the sum of the price elasticities of demand and supply. Since the numerator is generally quite small and in any case not much larger than the price elasticity of demand, the low supply elasticity does not necessarily imply that farm incomes will be more unstable over the business cycle than the incomes of other producers, even producers of those products with a perfectly elastic supply function.

It is true, of course, that when demand declines for reasons other than a decline in national income, the low price elasticity of supply is a curse if it is accompanied by a low price elasticity of supply. A similar statement may be made when the supply function shifts due to variables beyond the control of man.

Don Kaldor: Most American economists have been well nutured in the virtues of international specialization and trade. Among agricultural economists few have felt comfortable about farm programs that drive a wedge between internal and external prices. Consequently, it is a rare occasion when we hear one of our professional colleagues purpose a program of export dumping as a long-range solution to the farm surplus problem.

Professor Bronfenbrenner has presented a streamlined version of the old McNary-Haugen plan with its two-price system and equalization fee. The new version incorporates several additional features, however. It requires advance public announcement of specific export sale schedules. It lays down a general rule for determining the quantity to be offered. Losses on export sales would be financed by public funds and an equalization fee levied on producers. The proportions would be adjusted according to some measure of the deficiency in

aggregate demand. It provides for flexible tariff rates, and for certain restrictions on the use of bilateral agreements.

On the whole, these new features make a substantial improvement in the original plan. The provisions covering export sale schedules would help to reduce uncertainty and add some order to the disposal process. The suggestions on financing recognize the role of expenditure in generating income and the opportunity to induce a countercyclical effect. The restrictions imposed on the use of bilateral agreements recognize some, but not all, of the effects which export dumping can have on our international relations. But why impose these restrictions only on bilateral arrangements for export dumping? Since the objectives of the proposal are not made explicit, some question can be raised about the alleged advantages of flexible tariff rates. Under the assumptions made, any addition to domestic supply resulting from imports would necessitate an equal increase in the quantity dumped abroad. Therefore, encouraging low-cost production in exporting countries could not produce any direct gain for the US economy. Any gains made possible by lower costs would accrue to other importing countries. Nevertheless, as export dumping programs go, the proposal has considerable merit.

In setting the stage for his recommendations, Professor Bronfenbrenner warns against simplifying the issues by assuming as our goal of international economic relations a set of free competition and free-trade policies. But is the critical question really one of free competition. I suspect most economists are more concerned about the effects of export dumping on allocative efficiency than on free competition and free trade per se. The important question seems to be whether we are going to sacrifice some of the gains from a better allocation of resources implicit in a long-range dumping program.

Competitive markets are an institutional device for co-ordinating and integrating economic activities. When competition is perfect, the conditions for allocative efficiency are automatically satisfied. However, if competition is imperfect, a closer approximation to allocative efficiency might be achieved under arrangements involving a greater degree of government influence over the administration of resources. The condition that internal and external commodity values be related is a requirement of allocative efficiency, not free competition. Perhaps Professor Bronfenbrenner is saying that we should not be too concerned about over-all allocative efficiency.

He suggests that we focus on a new kind of multilateralism, one that involves competition between countries (which apparently means governments), but not international competition between producers and consumers. Does he mean that we ought to forget about the gains from a more efficient allocation of resources in world production and concentrate on the strictly short-run gains from exchange? Is it not true, however, that the gains from international specialization in production are really the significant ones?

The point is made that world prices would be much the same with export dumping as with free domestic markets. In the short run, this is likely to be true with commodities such as wheat and cotton. Under export dumping, however, there is likely to be a smaller long-run effect on domestic production.

When we are concerned with allocative efficiency the output effects become important. But free market pricing may not be sufficient to induce the amount of adjustment needed to establish a long-run balance. Export dumping, like other beggar-my-neighbor policies, tends to shift the burden of adjustment to other countries. It provides a powerful incentive to retaliation and economic warfare. Moreover, it is inconsistent with our postwar efforts to strengthen the free world.

Why has Professor Bronfenbrenner cast his solution to the farm surplus problem in an export dumping mold? The answer he gives is that other solutions fail to meet the test of political acceptability. Accordingly, he has excluded from consideration all solutions involving changes in support prices, adjustments in production, subsidies, and nutritional programs.

These techniques, as well as export dumping, all have been used to deal with problems of excess market supply. The emphasis placed on each has varied with changes in Congressional restrictions, the size and nature of the problem, technical suitability, and other factors.

What role does Professor Bronfenbrenner assign to his proposal? Is it conceived as an exclusive surplus control program? If the answer is no, is it considered a marginal program—one to be used only when other programs fail to eliminate a surplus? The answers to these questions have a bearing on its quantitative effects.

The proposal is designed with an eye to the storable products. Wheat and cotton are two of the three commodities mentioned. They are also the commodities that have been in most trouble under the support programs. Between 1951 and 1954, wheat stocks increased 250 per cent and cotton stocks rose 240 per cent. A decline in export demand was largely responsible. But during the past year important production adjustments have been made in wheat and cotton.

Under the marketing quota programs, almost 19 million acres have been diverted to other crops. Further diversions are planned or in effect for the coming year. With average weather conditions in 1955, wheat production is expected to fall short of meeting foreign and domestic demand at near current prices. These adjustments in production will go a long way toward correcting the recent short-run disequilibrium in the markets for these products. What is more, they were politically acceptable.

Obviously these programs are shifting the burden of adjustment to other crops. Since a large part of the diverted acreage has gone into feed grains and pasture, the effects ultimately will be transmitted to livestock. However, most of the commodities involved are not subject to mandatory price support. The Secretary of Agriculture already has announced reductions in support levels for a number of the commodities affected. Will lower prices prompt new Congressional action? Will it mean a general control program, a program to subsidize consumption, use of direct payments, greater reliance on export dumping, or some combination?

Recent passage of the Agricultural Trade Development and Assistance Act of 1954 might suggest that the emphasis would be on export dumping. This

was enacted by a Republican controlled Congress, and the Republicans traditionally have not been very international-trade-minded. On the other hand, the same Congress passed the Agricultural Act of 1954 which provides some flexibility in support levels for basic commodities beginning in 1955. What the new Democratic Congress will do to this legislation remains to be seen. But it would not be too surprising if it placed less emphasis on export dumping and more on production control.

At the present time, general use of direct payments is on the politically unacceptable list. However, their popularity seems to be on the increase. The recent Republican Congress authorized direct payments as a method of support for wool. This is an interesting development in view of the close association of this method with the plan proposed by Mr. Brannan. Currently, nutritional programs, except for school lunch and relief donations, do not have widespread support. But who can say with assurance what methods will be politically acceptable in the future. If broadly conceived and effectively carried out, the new farm and home planning program may prove to become an important adjustment mechanism.

Designing an optimum dumping program is a legitimate analytical problem, given the objective to be maximized and the restrictions to be imposed. But it would be unfortunate indeed if we were to confine our analyses and discussions of farm policy to what momentarily might appear to be politically expedient. As long as there are gaps in people's knowledge and imperfections in our system of representative government, we should not be overly concerned about immediate political acceptability.

LONG-TERM TRENDS IN INTERNATIONAL TRADE

SECULAR MOVEMENTS IN THE TERMS OF TRADE

By ROBERT E. BALDWIN
Harvard University

Interest in the problem of economic development has stimulated the study of long-run shifts in international terms of trade. The major purpose of these investigations, of course, is to analyze the economic forces which have caused the observed movements in these trading terms. However, before this analysis can be pursued with clarity and accuracy, two questions must be answered. First, what is the significance in a real income sense of the various measures proposed as indicators of the concept, "terms of trade," and what are the comparative merits of these measures? Secondly, how well do actual trade statistics measure these various analytical concepts? This paper is concerned with these two questions.

Concerning the matter of the real income or "welfare" implications of shifts in the terms of trade, the general position of major writers from at least the classical period to the time of Professor Taussig has been that a change in the terms of trade is presumptive evidence of a change in the amount of gain from trade.[1] Indeed, a rise in the ratio of export prices to import prices for a country has long been designated as a "favorable" shift in this price ratio. However, it should be noted that these earlier economists generally added that the presumption is subject to the absence of certain countervailing factors.

Although modern authors in international trade theory such as Professors Viner and Haberler are considerably more cautious concerning the welfare significance of changes in the terms of trade, there is still a large group of writers who are prepared to attach significant welfare connotations to movements in the usual measures of the terms of trade. The literature is full of references to the real income hardships which industrial nations will face if the ratio of their export to their import prices declines in the next twenty-five or fifty years. And the representatives of the underdeveloped countries also have been ready to proclaim the welfare implications of the past trend in the terms of trade. The following remark by the Chilean delegate to the Economic and Social Council of the United Nations (as reported on page 329 of the *Official Records*, Fourth Year, Session 8, 1949) typifies one posi-

[1] Jacob Viner, *Studies in the Theory of International Trade* (New York, 1937), p. 555.

tion: "But the deterioration, over a long period, of the relation between prices of raw materials and those of manufactured goods must be borne in mind. The result was a constant decrease in purchasing power and capacity for development in the countries producing raw materials."

In view of this wide association of the terms of trade with the concept of economic welfare and also the warnings of most outstanding theorists in international trade that there are some limitations on the employment of this measure for such purposes, it may be useful to analyze the welfare meaning of changes in the terms of trade a little more carefully. The early classical writers refer to the terms on which a nation trades by comparing the number of units of productive services of a foreign country whose product exchanges for the product of one unit of the productive services of the home country. Being dominated by a real-cost theory of domestic value (although asserting its inapplicability in the international sector), it was only natural for the classical writers to express the terms of trade in this fashion. Professor Viner called this measure of the terms of trade the "double factorial trading terms" (*op. cit.*, page 561), while Professor Robertson has labeled them the "true" terms of trade ("The Terms of Trade," *International Social Science Bulletin,* Spring, 1951). However, since these early writers generally assume constant and historically stable costs, they frequently use the commodity terms of trade, i.e., the ratio of export to import prices, as a shorthand representation of changes in this more fundamental concept. Today this is the measure which almost invariably is utilized in statistical analyses of international trading terms.

Early writers relate changes in the terms of trade to changes in real income in only a general way. Ricardo, for example, argues that the gains from trade consist of an increase in the mass of commodities and therefore in the sum of enjoyments, and he merely implies that an increase in the ratio of export to import prices leads to an increase in these enjoyments. However, J. S. Mill, who has exerted a powerful influence on subsequent study in this field, goes much further (*Principles of Political Economy,* Book III, Chapter 18). He wishes to measure the gains from trade exactly, in order to explain the manner in which these gains are divided among the trading parties. Taking a simple two-commodity–two-country model, Mill asserts that the differences in the opportunity cost ratios between two countries is an index of the total gains from trade. Therefore, the relation of the commodity terms of trade with these cost ratios shows the manner in which this total gain is divided between the two countries.

It should be noted that Mill is concerned with changes in the division of trading gains, not changes in the absolute gains to each party.

Only if the cost conditions remained the same in each country would he be willing to correlate the two. For example, when he assumes an increase in productivity in one of the countries and discusses the possible resultant deterioration in this nation's trading terms, he refrains from asserting that the country has suffered an absolute loss. Mill seems to recognize quite clearly here the inadequacy of a change in the commodity terms of trade as an index of a change in the absolute gains from trade.

Mill, of course, realizes that in order to connect the terms of trade and real income, one first of all needs a method of measuring changes in a nation's welfare. Moreover, for Mill the task is made especially difficult, since he wishes to explain how the total gains from trade are divided among the trading parties. Therefore, he needs an absolute measure of trading gains.

His particular measure of these gains, i.e., differences in opportunity cost ratios, is entirely unacceptable to present-day economists. It inadequately accounts for both the total utility derived from consuming various combinations of the two commodities and the total disutility involved in producing the items.

Moreover, almost all modern economists feel that there is no completely satisfactory manner of accounting for these factors and thus for measuring changes in real income or welfare in an absolute sense. Today, it is usually assumed that utility can only be measured in an ordinal sense. Thus, modern welfare economists only make statements concerning the direction of a welfare change, and then only under rigid assumptions. For example, as far as a country is concerned, it is said that, if tastes remain constant and if there are more of all commodities (or more of some and no less of others) in one position than in another, this indicates a potential increase in real income. The word potential should be stressed, since the question of the distribution of income bars any outright statement unless assumptions concerning interpersonal utility comparisons are made. Of course, if tastes change, they would not make even this weak statement.

In view of these objections, Mill's use of opportunity cost ratios as an index of the gains from trade and the commodity terms of trade as an indication of the way gains are divided must be rejected. Furthermore, the whole theoretical concept of the gains from trade is of little practical significance. All agree that the concept deals with the difference in some welfare sense between the collection of goods a nation actually produces and consumes with the existence of trade and what it would produce and consume in the absence of trade. Setting aside the problem of finding a measure of absolute welfare, it still would be impossible to determine the no-trade position in actual practice. The only

concept that one can discuss in the real world is a small change in a country's real income as the actual trading situation varies. Such changes can be quite different from a change in the theoretical meaning of the gains from trade.

The basic classical concept of the terms of trade, i.e., the double factorial terms, makes intercountry comparisons of these actual real income changes in the international sector. If one country's double factorial terms improve and thus its trading partner's (assuming there is only one) deteriorate, the interpretation is that the first country has gained more (or lost less) than the second country. This, of course, rests on the assumption that the welfare change of one country can be compared with that of another. But if we assume for the moment that utility is measurable in a cardinal sense and comparable among countries, this measure could give the wrong answer. For example, taking two countries (treating them as individuals), two commodities, and assuming that both countries have the same tastes, it is quite possible that if one of the two countries suffers a deterioration in its double factorial terms of trade—resulting, say, when there is a proportionate increase in productivity in the export industry of each country—this country could increase its utility more in a cardinal sense than the country reaping the better terms. For, while the country with the improved trading terms increases its imports (in physical terms) proportionately more than the other nation, this does not mean its utility for these imports increases more. One should not assume cardinal utility changes are proportionate to quantity change.

Professor Prebisch, for example, appears to illustrate this misleading type of conclusion when he complains about the secular fall in the commodity terms of trade of the underdeveloped countries. (United Nations, Department of Economic Affairs, *The Economic Development of Latin America and Its Principal Problems* [Lake Success, 1950].) He argues that, even though productivity in the export industries of developed nations has increased faster than that in underdeveloped countries, the commodity terms of trade have moved against the peripheral nations. Therefore, he concludes, "while the centers kept the whole benefit of the technological development of their industries, the peripheral countries transferred to them a share of the fruits of their own technical progress." Quite clearly he means that the real income gains through trade in the peripheral countries have not been as great as in more developed nations. But, accepting his assertion on the actual movement of the commodity terms of trade, his conclusion by no means necessarily follows. A major reason for the declining export prices of the peripheral countries relative to the export prices of the center would seem to be a high price and income demand elasticity for manufactured

products and a low price and income demand elasticity for primary commodities. The peripheral countries together with the industrial nations helped to keep up the prices of industrial commodities by their comparatively large increases in demand for these goods as real income rose. Although the quantity of imports of industrial nations rose relatively more than those of underdeveloped countries, perhaps the result would be that the latter group received a greater increase in utility for their imports than the developed nations, if these utilities could be measured in a cardinal sense and could be compared.

While most economists are reluctant to employ terms-of-trade measures such as the double factorial as indications of the relative trading gains among nations, many seem willing to give meaning to shifts in the terms of trade merely as an index of changes in the direction of a particular country's real income position. The commodity terms of trade, the income terms of trade, and the single factorial trading terms are examples of measures utilized for this purpose. But there are severe limitations on the range of welfare statements that can be made on this level without selecting some social welfare function for the country. Moreover, even with such a function, none of the above measures always indicates the direction of change of a nation's real income as affected by foreign trade. Nevertheless, there are differences in the merits of these various terms-of-trade concepts for long-run studies, given some judgment concerning the distribution of income within the country and thus a well-defined social welfare function.

Changes in the commodity terms of trade can be completely misleading. Frequently, a country, such as Great Britain during the first half of the nineteenth century, has been carried into international prominence on the wave of a secular decline in its commodity terms of trade. And the history of many a successful business is one of striving for more unfavorable terms of trade. The point, of course, is that the commodity terms of trade fail to take explicit account of changes in export productivity and changes in the volume of exports.

The influence of classical thinking is too great in regard to this matter. In their international trade analysis these writers generally assume, first, a constant supply of resources operating within a given state of technology and, secondly, a purely competitive, fully employed, domestic economy where all the optimum marginal conditions are satisfied. Under these conditions, a change in the export-import price ratio has some claim to be considered as an indication of a change in a country's real income in the international sector. But these assumptions are completely inappropriate for long-run analysis and, for that matter, even for most short-run analysis. Take the matter of the optimum conditions. Obviously, every factor does not earn the same return in all

of its possible different uses in both the developed and, particularly, the underdeveloped nations. A country may expand its exports partly by drawing on factors in less productive employments, incur an unfavorable movement in its commodity terms of trade, and still raise its real income significantly. This has been a frequent pattern of economic development. To study the long run with a series which can give a rough idea of what is happening only when population, capital stock, and the state of technology remain the same is equally misleading.

Another aspect of the static classical model is that it ignores the dynamic repercussions of the international sector on the domestic economy. An increase in the importation of some item essential to domestic development may force import prices up and cause a temporary decline in real income. But the long-run effect of these imports may be to add greatly to the real income in the domestic sector of the economy. In brief, a change in the commodity terms of trade is a useful indication of a change in real income as affected by foreign trade only if all other things remain the same. But in the long run, changes in the commodity terms of trade frequently are accompanied by other changes in the international sector which counter the real income effects due merely to changes in the commodity terms of trade. To concentrate upon the terms-of-trade element in real income and to exclude other relevant variables is highly inappropriate in analyzing long-run shifts in real income.

The widely expressed view on the part of the representatives of the underdeveloped countries that measures must be taken to stop the secular decline in their commodity terms of trade may well lead to disastrous policy decisions. And the same applies to those in the developed nations who seem obsessed by a fear of long-run deterioration of their commodity trading terms.

The obvious limitations of the welfare conclusions to be drawn from changes in the commodity terms of trade have led to a number of alternative measures designed to rectify these drawbacks. One measure, which can be computed quite as easily from the available statistics on trade as the commodity terms, is an index of the total value of exports divided by an index of import prices. This indicates changes in the volume of imports which can be purchased through the export trade. It has been termed by Viner as the total gain index (*op. cit.*, page 563); by G. S. Dorrance as the income terms of trade ("The Income Terms of Trade," *Review of Economic Studies*, 1948-49, No. 39); and (perhaps most appropriately) by the Economic Commission for Latin America as the capacity to import (Secretariat of the Economic Commission for Latin America, *Economic Survey of Latin America, 1949*). However, while it must be granted that a recognition of the volume of trade

is important for an appraisal of trading gains, the attempt to combine this element with the price element in a single composite measure can lead to quite incorrect conclusions as a measure of the direction of real income charge for a country. For example, if the export price level remains unchanged while the quantity of exports increases and the price of imports also increases proportionately, the index will not change. Yet simple, static indifference curve analysis tells us that these are precisely the conditions under which an individual would be worse off. *Ceteris paribus,* a rise in this index could mean either an improvement or worsening of a country's real income position. For this reason it is a poor measure of real income shifts.

Another measure, which attempts to include the influence of productivity in determining the direction of gains, is the single factorial terms of trade: the commodity terms of trade multiplied by an index of the productivity of the factors of production in the export industries. Professor Robertson *(op. cit.)* feels that this measure is the one best suited for a discussion of changes in a country's real income as affected by foreign trade. One problem with the concept, as has been stressed recently by Ely Devons, who has statistically measured the single factorial trading terms for the United Kingdom over the last twenty years ("Statistics of the United Kingdom Terms of Trade," *The Manchester School,* September, 1954), is the ambiguity associated with the term, "the productivity of a unit of the factors of production." It is difficult to define. This obstacle, of course, also is present with the double factorial terms of trade. Efforts in this field have been confined to measuring the productivity of labor—the measure Devons employs—and are not entirely satisfactory for the purpose. However, even if this measure is used in computing the single factorial terms of trade, an investigator is faced with a lack of adequate data in this area for anything but recent years. Furthermore, like the other measures, this one cannot always reflect the true direction of welfare change, even treating a country as an individual with well-defined indifference curves. It should be noted, however, that the last two measures of the terms of trade can rise and fall for everyone simultaneously.

Do all of these objections force one to the conclusion that all efforts to discuss the effects of long-run changes in foreign trade on real income should be abandoned? I would say it does not. Modern welfare economics does not conclude that almost all efforts to measure changes in real income are futile. It merely points out that on the basis of very weak value judgments, which are almost universally accepted, one cannot go very far in making definite statements. But there are many stronger value judgments involving assumptions concerning interpersonal comparisons of utility which are acceptable to the large majority

of policy-makers and affected parties and under which many definite welfare statements can be made. The economist must employ these judgments, if he wishes to have a significant role in policy making or in interpreting history in anything but a rather trivial sense. (Judgments concerning the welfare significance of new commodities and changes in tastes are also necessary, if any definite statements are to be made.) However, he should explicitly state these judgments and also point out the welfare conclusions which follow from different sets of these interpersonal utility value judgments. Then the reader can make a conscious choice in deciding what real income conclusions he wishes to accept. Too often both the writer and the reader are not consciously aware of the value judgments upon which the conclusions entirely depend.

These remarks, of course, are relevant to all studies of changes in real income. But, as has been noted, the investigator in the terms-of-trade area is faced with additional difficulties associated with the narrowness of his topic. It would seem to me that what little information can be gleaned from the foreign trade sector should not be further constricted by merely studying the ratio of export to import prices. It does make a difference to a nation whether its import or its export prices are changing; to withhold the knowledge of this information from the reader by presenting only a ratio (as is often done) appears unwarranted in view of the limited significance of changes in the ratio. Furthermore, a study in this field should be implemented by the use of export and import volume indices, productivity changes in the export and internal sectors of the concerned economies, and the host of other economic indicators which help to make up a comprehensive study of the total economy. In other words, we should not concentrate merely on the international sector if we wish to make meaningful statements about real income changes which are caused by foreign trade. The total economy should be studied in the context of a dynamic, non-optimum view of the development process. Nor should volume and productivity figures be combined with price data into single ratios. They can all be misleading. Certainly every bit of what can be seen by these ratios can be discovered without them, plus a good deal more.

It should be noted that these criticisms relate to the employment of the various terms-of-trade measures as indicators of long-run gains in foreign trade. There are, of course, other purposes for which these ratios are used—such as in studying balance-of-payments problems and capital movements. For such purposes these measures may serve as useful tools. However, in such analyses, the limitations of these concepts as real-income measures should be explicitly stated.

In addition to the many theoretical limitations involved in relating

changes in trading terms to changes in real income, there are a host of statistical problems connected with long-run studies of the terms of trade—particularly those dealing with pre-World War I figures. A major difficulty, of course, is the lack of comprehensive and accurate data. For example, Werner Schlote in his study of the foreign trade of Great Britain (*British Overseas Trade from 1700 to the 1930's* [Oxford, 1952]) employs Jevon's commodity index—an unweighted series of only forty commodities—in his computation of current import values from 1814 to 1854. This import value series, and the import price index he derives from it with the aid of a volume series, must be regarded as a very crude trade measure. Professor A. H. Imlah ("Real Values in British Foreign Trade, 1789-1853," *Journal of Economic History,* November, 1948, and "The Terms of Trade of the United Kingdom," *Journal of Economic History,* November, 1950) has pointed out some of the inadequacies of these estimates, while also doing much to improve them. But, as he notes, price and value series for these years can only be regarded as very rough measures of the true relationships.

However, the drawbacks of series used to depict trading terms for later and even quite recent years are not quite so obvious. H. Staehle ("Some Notes on the Terms of Trade," *International Social Science Bulletin,* Spring, 1951) notes that in the case of the foreign trade of the Belgium-Luxembourg Customs Union during 1948 where complete records (representing about 25,000 punched cards) were kept, import and export price indices varied significantly between a sample based on all commodities accounting for at least 1/1,000th of the total value and one based on 1/10,000th of total value. In other words, these price series seem to be highly sensitive to variations in coverage.

Furthermore, a price series based on a limited sample of similar commodities throughout a fairly long period, such as A. G. Silverman's index of British export and import prices from 1880 to 1913 ("Monthly Index Numbers of British Export Prices, 1880-1913," *Review of Economic Statistics,* August, 1950), tends to be biased in an upward direction because of the omission of new commodities introduced during the period examined. It is reasonably well established that the price history of a new product, relative to previously existing commodities, is one of rapid decline in its early stages of production. While new items probably do not enter international trade as soon as they do domestic trade, it would seem that the exclusion of these products from a commodity sample underestimates the relative price decline of the total commodity list. This factor, of course, applies to both import and export indices. An intensive study would be needed to determine whether the upward bias was greater on the import or the export side for a particular country in a particular period; e.g., Great Britain from

1880 to 1913. But since the composition of Britain's exports underwent a greater change than its import trade in this period, the suspicion is that this factor tends to cause a greater upward bias to export prices than to import prices.

A related point is the choice of weights in the computation of a price index. For a given array of commodities, price indices based on beginning-year weights tend to have an upward bias compared to price indices based on end-year weights if the changes in the prices and the changes in the quantities are negatively correlated, i.e., price changes result from changes in cost conditions, and a downward bias if the changes in the prices and the changes in the quantities are positively correlated, i.e., price changes are due to relative changes in demand. As R. G. D. Allen observes (*International Trade Statistics* [New York, 1953], page 195), the usual case with price indices of actual time series is that the index employing beginning-year weights shows an upward bias compared to one using end-year weights.[2] However, a study of the direction of the bias and its impact on export prices compared to import prices should be made on the widely used British figures.

Similar problems to those mentioned above also arise with the widely used procedure of computing price indices on a unit value basis. Although new commodities automatically enter the broad category groups in both the volume and actual value series, in this measure of price change, they are not weighted by their correct prices. Analogous inaccuracies also occur when there are compositional shifts within the promiscuously broad unit value categories—a frequent occurrence in any long-run series. And, of course, this index number is also subject to the relative bias problem associated with the choice of weights.

The matter of accounting for quality changes is still another obstacle to be faced in a study of the terms of trade as in almost all studies of price and quantity series. While there is no satisfactory method of handling the problem, all agree that a correct picture cannot be obtained without recognizing their great importance. In a terms-of-trade study the significance of this point lies in the generally accepted view that quality improvements have been greater in manufactured products than in primary commodities. If this is true, it tends to impart to the typical statistical measure a systematic bias which makes changes in the terms of trade of nations exporting manufactured goods and importing primary goods more favorable than they actually are. Certainly, this point applies to the example of the much-cited British data from 1870 to 1913.

[2] Viner in his study, *Canada's Balance of International Indebtedness, 1900-1913* (Cambridge, 1924, pp. 231-232), found that Canada's export price index based on beginning-year weights rose to 135.6 in the end year compared to 120.2 for the price index based on end-year weights.

A final point related to this British data is that the United Kingdom values imports c.i.f., i.e., inclusive of transportation charges, while it values exports f.o.b., i.e., exclusive of these charges. Therefore, a change in British import prices need not entirely reflect a change in the prices which foreigners received, since shipping costs on imports were in part paid by British importers to British shippers. Furthermore, on the export side there is no provision for the inclusion of British shipping services purchased by foreigners. A terms-of-trade index which included both merchandise and shipping services would give a more accurate picture of Britain's commodity terms of trade. An estimate of the importance of this point in the period 1870 to 1913 is as follows. Professor Imlah's index of net merchandise import prices fell 32 per cent and his index of domestic export prices 18 per cent between these two years. Thus Britain's commodity terms of trade rose 19 per cent (Imlah, *op. cit.*). However, net shipping earnings during this period were equal to about 22 per cent of domestic exports. Furthermore, freight rates fell about 50 per cent between these two years. (A. K. Cairncross, *Home and Foreign Investment, 1870-1913* [1953], page 176.) A rough estimate of merchandise and shipping terms of trade can be made if the import index is left as it is but shipping services are introduced in the export index. This new index increases only about 12 per cent between the two years rather than 19 per cent.

These statistical difficulties reinforce the analytical arguments urging a cautious use of long-run export and import price series. It is bad enough that the real income significance of changes in the commodity terms of trade is frequently misinterpreted, but it is even worse that the data on which these conclusions are drawn may not even indicate the true directional change. For example, it has been generally asserted that Great Britain's commodity terms of trade improved between 1870 and 1913. But an appraisal of the limitations of the statistics on which this conclusion is based leads one to doubt whether this statement is really true.

THE LONG-TERM FUTURE OF UNITED STATES IMPORTS AND ITS IMPLICATIONS FOR PRIMARY-PRODUCING COUNTRIES

By HENRY G. AUBREY
Federal Reserve Bank of New York

I. *Introduction*

Recent discussions of future United States imports have been largely focused on specific policy aspects: our requirements of strategic materials; "trade, not aid" as a solution—or a palliative—for the world's dollar problems; tariff policy and its relation to domestic production; etc. The present paper is not concerned with problems of United States import policy. It discusses, rather, the significance of certain prospective or inferred changes in the volume and the real value of our imports. Summarizing a series of projections made by the writer in a study prepared at the Federal Reserve Bank of New York,[1] this paper first discusses a method of estimation that is largely based on individual commodity studies rather than on aggregative trend projections. Next, the actual estimates and their implications for the United States' propensity to import and for the future of the terms of trade are taken up in turn. It will be found that both the downward trend of our import-income ratio and the deterioration of primary-product prices relative to those of manufactures have been reversed. Finally, the implications of a large increase in United States imports for the economic development of primary-producing countries will be discussed. The argument suggests that the marginal importance to developing countries of increased exports is much greater than is usually realized; moreover, the operation of a number of "multipliers" tends to raise the cumulative benefits of increases in exports far above the initial value increments.

II. *A New Attempt at Projecting the Value of United States Imports*

Methods of estimating the future demand for imports have been the subject of much professional discussion. A session devoted to this topic at the 1952 AEA meetings (*Papers and Proceedings*, May, 1953, pages 135-166) once more exemplified the difficulty of deriving elasticities and import functions from historical time series. Conceptual and statistical problems, however, are not the only obstacles. No long-range trend projection from any given historical experience can yield satis-

[1] "The Secular Increase of United States Imports and World Trade" (Balance of Payments Division, May 13, 1954, mimeographed).

factory results if the relationship between any of the basic variables is subject to significant change.

Recent investigations of our raw material base reveal that the last decade marked the beginning of a structural change that is characterized by a widening gap between the growth rates of demand and of domestic supply of several major commodities. Resulting shifts in the supply elasticities of domestic and foreign products tend to reduce or void the usefulness of rigid projections of aggregate import propensities derived from structurally different periods. The purpose of this paper is not to argue this view at length, although the traditional preoccupation with short-term elasticities has tended to divert attention from the factors involved in long-term estimation.[2] This point has had to be made, however, in order to explain the writer's tendency to rely only to the smallest possible extent on aggregative trend projections in his attempt to estimate the value of future imports.

As a partial substitute, the import values of about thirty major commodities, which account for approximately two-thirds of our imports, were individually projected. The estimation of import volumes followed closely the course adopted by the Paley Commission (*Resources for Freedom*, June, 1952) which, it will be recalled, estimated imports as the difference of projected demand over prospective domestic supply. In this respect, an important underlying assumption should perhaps be made quite explicit; namely, that import demand is in fact a residual. This implies that imports are drawn upon—even in the long run—only to the extent necessary to supplement domestic supply; in other words that, on the whole, imports are marginal to the domestic production of competing products.

This tacit assumption has found support in recent publications concerned with United States demand for imports.[3] In addition to the statistical evidence mentioned therein, this proposition actually has a solid foundation in American import policies. The interplay between protec-

[2] We really know little about long-term elasticities except that they are probably greater than in the short run. It is surprising that Professor Harberger should claim in his discussion below that demand elasticity is "well below unity." He was prominent among the economists who showed that all known methods lead to underestimation. (See Arnold C. Harberger, "Index Number Problems in Measuring the Elasticity of Demand for Imports," *Econometrica*, July, 1950, p. 275, and Fritz Machlup, "Elasticity Pessimism in International Trade," *Economia Internazionale*, February, 1950 pp. 127 ff.) Moreover, the most elaborate study of US imports yet made points to elasticities very close to or even exceeding unity, not .5 as Professor Harberger claims. (See J. H. Adler, E. R. Schlesinger, and E. Van Westerborg, *The Pattern of United States Import Trade since 1923*, pp. 70 ff.)

[3] See G. Lovasy and H. K. Zassenhaus, "Short-Run Fluctuations in United States Imports of Raw Materials, 1928-39 and 1947-52," International Monetary Fund, *Staff Papers*, October, 1953, p. 281; Arnold C. Harberger, "A Structural Approach to the Problem of Import Demand," and Hans P. Neisser, "The United States Demand for Imports," both in AEA *Papers and Proceedings*, May, 1954, pp. 146 and 154 f. Also discussion by J. H. Adler and H. K. Zassenhaus, *ibid.*, pp. 160 and 164.

tionist forces and countervailing interests and considerations has brought about a precarious, yet curiously enduring, balance. As a result, domestic producers of raw materials can count on a market for most of what they can produce within a fairly narrow range of average costs, while the economy is spared the cost of extreme protection. The dust of battle frequently seems to obscure the long-range operation of such a system of checks and balances in United States postwar policy. Sometimes, though rarely, this principle manifests itself in as explicit a fashion as the well-known recommendation of the National Petroleum Council that imports should supplement but not supplant domestic production. It appears realistic and not at all unreasonable to incorporate such a sociopolitical stabilizer as a datum into a system of foreign trade, in the form of an assumption that imports are marginal to domestic production.

Yet this relationship between domestic output and imports cannot operate independently of the price mechanism. If demand increases faster than domestic output and prices tend to rise, imports become more attractive within a given tariff and freight rate structure. Conversely, if prices fall, a specific tariff or a rigid freight component imposes a relatively greater burden on the foreign product and tends to shift the competitive advantage in favor of the domestic supplier. Similarly, the forces that make for substitution of one commodity for another can only be appraised in conjunction with price considerations. It therefore seems strange that the Paley Commission excluded relative price changes from its model, by adhering to the price structure of 1950. As the Commission was only concerned with import volumes, this assumption was perhaps not too harmful, especially since in some of the Commission's commodity studies the substitution effects of relative price changes were not entirely ignored. In projections of import values, however, relative price shifts can hardly be neglected without impairing the usefulness of the results from a realistic angle. This deficiency becomes apparent in an earlier attempt at translating the Paley estimates into value terms. (See Eugene R. Schlesinger, "The Long-Run Outlook for United States Merchandise Imports," International Monetary Fund, *Staff Papers,* February, 1954.) The choice of 1950 as a base year makes the assumption of unchanged price relations particularly unrealistic, since the Korean emergency had distorted the price structure in a singularly arbitrary manner. Whenever Schlesinger uses 1950 import values as the basis for projections, the distortions of trade volumes in that year tend to add to the disparity because the second half was already affected by the scramble for imports that began after the Korean invasion. Moreover, apart from certain recent important commodity developments, Schlesinger ignores sizable revisions in the population and

labor force estimates that have been made since the Paley report was published. As a result of such discrepancies and some differences in assumptions, my value projections range from 10 to 35 per cent higher than Schlesinger's interpretation of the volume projections in the Paley report.

On the other hand, an attempt to project commodity prices over long periods of time appears, at first sight, to face formidable obstacles.[4] Upon closer scrutiny, however, a number of specific factors tend to narrow the range of contingencies within the empirical economic framework that characterizes individual commodities. While it is not possible to summarize here the considerations set forth at great length in my earlier study, it can be said that the key to price estimation was found in the matching of the prospective domestic supply with estimated total demand, with due consideration to long-term technological trends.[5] Through numerous discussions with commodity specialists in industry and government, a fairly broad range of prices, not a single price, was established for each commodity in accordance with a fair consensus of experts, based on a partly intuitive, but to them quite tangible, appraisal of long-term cost trends in their industries. In line with the assumed marginality of imports, the lower limit of the range is determined by real domestic production costs, since the projected domestic output would not be forthcoming below a figure satisfactory to a requisite number of producers. Conversely, the upper limit of the range is reached when only a small increase of domestic output could be expected from a price rise to a point at which foreign imports would become available in sufficient quantity. Professor E. S. Mason, a member of the Paley Commission, has expressed the opinion that foreign reserves of metals are large enough to eliminate the likelihood

[4] It is essential to distinguish—as Professors Kindleberger and Morgan fail to do in their discussion below—between price estimation in the short and the long run. Daily commodity price changes are based on expectations that arise from imperfect knowledge of actual demand and supply. In the long run, supply elasticity is high and cost relationships are the prime determinant. It is therefore easier, not more difficult, to project price trends over the long term rather than for the next six months or so, especially if a reasonably broad range, not a single price, is assumed.

[5] Technological change can be projected with suitable precautions, since it is neither as erratic as Professor Harberger implies, nor as unpredictable as Professor Morgan believes. Industry experts are well aware of the "crucial technological elements in economic progress" to which Professor Harberger refers in his discussion below. The time table of technological change, especially in extractive industry, is not fortuitous but planned many years in advance. The technology of years hence has been on the drawing board or in experimental stages for a long time, and more remote possibilities for coming decades are continually explored. On the whole, very little that can become a sizable economic factor within the next twenty years is not already known in outline and thus accessible to appraisal by the experts. As Professor Harberger points out, the extent of change and its economic effects vary from industry to industry. This is why disaggregation is essential for realistic projections. The greater degree of aggregation that Professor Harberger seems to prefer would fail, precisely because we cannot expect that differential change can be "averaged" realistically and consistently.

of price increases (in real terms) during the next twenty to twenty-five years. (See "Raw Materials, Rearmament and Economic Development," *Quarterly Journal of Economics,* August, 1952, page 332.)

In the case of commodities not manufactured in the United States, similar factors that shape world supply and demand had to be substituted. For foods, the consumption of individually-projected import items was based on long-term trends of per capita consumption and on a population projection somewhat below the highest recent estimate of the Census Bureau.[6] Finally, in order to project the remaining one-third of United States imports not covered by individual commodity estimates, a modified system of trend projections was adopted, partly based on unpublished postwar coefficients computed in the Federal Reserve Bank of New York.

III. *The Outlook for United States Imports*

The Gist of the Projections. Table 1 summarizes the projections for a reasonably normal year in the 1970's when the United States gross national product would, by assumption, have reached a level of 615 billion in 1953 dollars, twice the level of 1950[7] and a modest figure in the light of recent official and unofficial estimates and targets for 1965. The value of United States imports in constant dollars about twenty years hence is estimated at from 2.5 to nearly 3 times the value of imports in 1948—the year of largest postwar imports before the Korean emergency. Using for comparison the values that are based on prices considered as "most likely" by the experts, this corresponds to an annual rate of increase of imports of 3½ to 4 per cent from 1948 to 1975. If petroleum, which accounts for 37 per cent of the projected increase during that period, is tentatively eliminated from the com-

[6] *Current Population Reports, Population Estimates,* Bureau of the Census, Series P-25, August 21, 1953, p. 5. Population in 1975 was assumed to reach 215 million. The census estimates range from 199 to 221 million, the lower part of the range being unlikely except in the case of relatively low economic activity. The highest estimate implies the maintenance of about the predepression age-specific fertility rate rather than the postwar birth rate to which Professor Mason refers in his comment on Colin Clark's population estimate of no less than 234 million in 1975. (See Colin Clark, "Afterthoughts on Paley," and Edward S. Mason, "Comment," in the *Rev. Econ. Stat.,* August, 1954, pp. 270 and 276.) According to the Census Bureau, all of its latest estimates may be considered conservative, and it will be recalled that all earlier census estimates had erred on the low side.

[7] The original table included three columns under each price assumption. These alternative estimates had to be omitted for reasons of space. (While the lower volume projections reduce the import total but very little, the higher assumptions would increase total imports for 1975 in the three columns of Table 1, respectively, by 2.0, 1.6, and .9 billion of 1953 dollars.) The three price columns refer to the range of prices established by the commodity specialists; the lower and upper ends of the range are perceived by the experts as possible but not very likely, while the price designated as "most likely" carries considerably greater probability weight. It should be noted that this range represents, as it were, the significant section of a probability range, in place of a single long-run price estimate; it is not meant to delimit the amplitude of short-term fluctuations, which might well be much greater.

TABLE 1

UNITED STATES IMPORTS—1975, 1948

	1975 (In Millions of 1953 Dollars)			1948 (In Millions of 1953 Dollars*)
	Low Price	"Most Likely"	High Price	
Crude Materials and Semimanufactures†				
Aluminum and bauxite	235	256	273	62
Copper	496	453	494	214

parison, the annual rate of increase of imports still remains above 3 per cent. Such a prospect appears of sufficient magnitude to encourage the following three main lines of speculation.

Growth Trends. The rapid increase of imports since 1949 for which the post-Korea import boom at first seemed to be alone responsible now appears merely to be the forerunner of sizable future growth. In fact, after the passing of the Korean emergency and in spite of a reduction of commodity prices, our imports were well maintained in 1953 and are

likely to show no more than a slight drop in 1954, our recent recession notwithstanding. In the perspective of our projections a further doubling of the recent import level by 1975 is well within the realm of possibility.

The postwar period appears to mark a distinct change in the rhythm of our imports, from a period of near stagnation to one of rapid growth. From 1926 through 1948 our imports barely grew at all in terms of constant dollars,[8] but on the basis of our projections they might increase by 3½ to 4 per cent annually from 1949 through 1975. This change of pace can be best, though only partially, understood against the background of our greater dependence on certain raw-material imports. Steeply growing imports of petroleum, iron ore, nonferrous metals, and many others are clearly in store. It is, however, noteworthy that offsetting factors are always present, so that—perhaps surprisingly—in our projections for 1975 the combined share of crude materials and semimanufactures in the total just barely rises above the 62 per cent mark reached in 1925-29. (Newsprint and burlap, classified as finished manufactures in United States statistics, were included in semimanufactures in this calculation, which was derived in current dollars from the source mentioned in footnote 8.)

The "Propensity to Import." While the Paley report foretold a rapid increase of raw material imports, it did not imply that the volume of imports would grow as fast as the gross national product. The inclusion of a greater variety of imports and the present method of projecting values instead of volumes afford an altogether different perspective. It now appears that the succession of declines of the import-income ratio that used to be considered a historic trend has been arrested and a further slight upward tendency may be expected for the future.

Since in the past much has been made of our "declining propensity to import," a few additional remarks on this issue may be in order. Table 2 presents the percentage ratio of total United States imports to gross national product in current dollars for the last eighty years and adds the ratio for 1975 implied by our projections. It appears that the historical decline took place in somewhat discontinuous steps, interrupted by lengthy periods of stability like that from the turn of the century to the Great Depression. In view of this progression, one might well wonder why this phenomenon should have been so commonly interpreted as a "secular" trend without adequate investigation into the specific factors which have been responsible for the decline in each individual historical period.

[8] Current dollars adjusted by United States wholesale price index, calculated on the basis of John H. Adler, Eugene R. Schlesinger, and Evelyn Van Westerborg, *The Pattern of United States Import Trade Since 1923* (1952).

Column (2) GNP: 1929–48 from *The Economic Report of the President*, transmitted to Congress January 14, 1953, page 165; 1952 from *Federal Reserve Bulletin*, November, 1953, page 1212. Imports for consumption 1929–40 from *Statistical Abstract of the United States, 1941*, page 527; 1948 from *Monthly Summary of Foreign Commerce*, January–December, 1948, page 22; 1952 from *Quarterly Summary of Foreign Commerce of the United States*, January–December, 1952, page 23.

One might expect that certain structural shifts which characterize the growth of the American economy would bring about a change in our import requirements. Technological displacement is frequently mentioned as a reason for lower imports, but this argument can be overdone, since technological change is not necessarily import-replacing, as it was in the case of silk and natural rubber, largely under the spur of wartime shortages. For instance, displacement of steel by aluminum in certain uses might well spell increased imports; so would a trend towards alloy steels requiring greater quantities of such imported additives as nickel, chrome, and others. At present, our advanced industrial technology tends rather to bring about a growing use of commodities that we cannot, or can no longer, produce at home in sufficient quantities, except possibly at steeply rising real costs.

The previously discussed marginality of imports may have been partly responsible for reversing the downward trend of the import-income ratio. Coincidental with the dollar devaluation in 1933-34, imports of crude materials and semimanufactures began to lag progressively behind industrial production, while the domestic output of import-competing crude and semimanufactured materials increased. (See G. Lovasy and H. K. Zassenhaus, *loc. cit.*, Chart 1, page 272 and page 286.) Although other factors also entered into the picture, it

would appear that imports were proportionately more affected by the decline in total demand and their share in raw material consumption shrank. By the same token one might also expect that rising incomes would call for a more than proportional increase in imports.[9] This appears to be precisely what we have been witnessing recently. A first substantial rise of the import-income ratio has already taken place, as Table 2 shows; although fluctuations will undoubtedly occur, the projections imply that no renewed decline need be anticipated for the long run and that a further slight increase may be in store.

The Future of the Terms of Trade. The extended range of projections adds perspective to another controversial problem: trends in primary commodity prices and the terms of trade of underdeveloped countries. It will be recalled that this topic has been frequently discussed in international meetings, especially of the United Nations, in relation to problems of financing economic development. A United Nations study (*Relative Prices of Exports and Imports of Underdeveloped Countries* [1949], especially page 121) claims to show that the prices of primary commodities have declined 40 per cent relative to those of manufactured goods over a period of seventy years preceding the second World War. Another report (*Economic Survey of Latin America for 1949* [1951], page 55 and following) suggests that there is an inherent tendency for this price relationship to deteriorate with each successive recession, a theory that is certainly not substantiated by the recessions of 1949 and 1953. The statistical basis for price series going back a long way is open to considerable doubt, and a more recent United Nations report (*Commodity Trade and Economic Development* [1953], page 12) by a panel of experts is much more cautious in its inferences and warns of drawing conclusions for the future from past tendencies.

On the other hand, secular changes of the terms of trade are undeniably of great importance to primary-producing countries as a determinant, not only of their national income, but also of their ability to import consumer goods and development goods. It is therefore relevant to note that the trend which turned progressively unfavorable to primary commodities in the decade preceding the second World War has since been decisively reversed. Table 3 shows the course of import unit values as an index based on the years 1937-40, and Table 4 re-

[9] A rising share of services in national income is often mentioned as a reason for a less-than-proportional rise in imports. But the share of services in United States national income is no longer rising. On the contrary, the share of services in total personal consumption expenditure declined from 40 per cent in 1929 to 34 per cent in 1953. (See *Economic Report to the President,* January, 1954, p. 172.) We are a nation of "doers"; thus even increased leisure does not necessarily mean a smaller share of goods. The contrary may be true—witness the do-it-yourself boom with its increased sale of tools and materials.

TABLE 3

UNIT VALUE INDICES OF SELECTED UNITED STATES IMPORTS BY COMMODITY GROUPS

(Average 1937–40 = 100)

	1948	1975		
		"Low"	"Most Likely"	"High"
Crude and semimanufactured materials	207.4	267.3	300.6	321.4
Crude and semimanufactured materials, excluding petroleum	197.0	198.3	220.7	243.0
Crude and maufactured foods	353.9	434.6	486.4	538.2
Total	233.3	292.7	330.6	357.8
Total, excluding petroleum	226.9	249.6	280.0	308.8

lates this index to one of unit values of United States exports of finished manufactures. It will be seen that by 1952 the terms of trade of crude and semimanufactured materials had improved about one-third above the prewar base. The price relationship of foodstuffs had turned nearly 200 per cent more favorable, largely owing to the unusual price rise of coffee and cocoa. On the whole, the terms of trade

SOURCE: Table 3.

of United States imports of the selected raw materials and foods had improved nearly 60 per cent above their prewar base by 1952. "Terms of trade" is here used to describe the price relationship of commodities —primary versus manufactured—rather than, as is customary, that of imports and exports of countries. They are based on the Paasche type indices of United States imports shown in Table 3.

This development restores to primary products the level of price

relationships in United States commodity trade that appears to have prevailed about forty to fifty years ago, depending on which set of statistics is used.[10] Moreover, the passing of the post-Korea commodity price boom, while affecting certain commodities materially, has not, on an average, brought about a return to prewar relationships. Most important, as Table 4 shows, the long-run outlook for the next two decades suggests that the improvement of the terms of trade over the prewar level is likely to be maintained and, possibly, even slightly increased.

As a result, one may feel encouraged to believe that the adverse trend of the depression, and possibly of earlier decades, has been reversed—not passingly but decisively. To use the word "permanently" in this connection would appear too bold, since temporary declines in line with the rhythm of world prosperity cannot be excluded. Thus instability may well remain a very real problem. Moreover, various commodities and, hence, different producer-countries must be expected to fare differently over time. However, the danger of secular deterioration of the terms of trade of primary products imported by the United States appears no longer as the inexorable threat envisaged by the interpreters of earlier data.

IV. *Implications of Increased United States Imports for the Economic Development of Primary-Producing Countries*

Greatly increased exports to the United States would appear to hold out alluring prospects to potential supplier countries. However, among the less developed primary-producing countries a suggestion that exports might be profitably increased meets often with distinct disfavor, largely based on adverse historical experience. Since the volume of exports depends on foreign demand, great fluctuations were experienced in the past, with disastrous results for economies that are dependent on export proceeds for nearly all their essential needs. In such countries, exports tend to be viewed as a symptom of imbalance, in contrast to the goal of greater diversification to which the underdeveloped areas generally aspire. Taking this widespread attitude into account, the following section analyzes the gains that greater exports seem to offer to the internal economy of primary-producing countries.

A near doubling of imports by the largest importer in world trade is bound to have profound effects on supplier countries. The impact will be greatest where the export sector provides a sizable share of the

[10] A long-term series computed by the Pan American Union puts the average price index of Latin-American exports of raw materials and foodstuffs relative to United States wholesale prices in 1953 at 105.7 (1900=100), approximately equal to the 1897 level. See "Terms of Trade of Latin America: Their Development and Prospects," September 15, 1954 (mimeographed).

national product. As a rule, therefore, the less developed primary-producing countries will be most significantly affected. However, in recent years some doubts have been cast upon the gains ultimately realized by such countries from foreign investment in export industries. (For example, H. W. Singer, "The Distribution of Gains between Investing and Borrowing Countries," AEA *Papers and Proceedings,* May, 1950, page 474 ff.) It may thus be worth while to review the opportunities that may arise for primary producers from a growth of exports to the United States as large as that implied in our projections.

In discussing the benefits of trade for the primary-producing countries, it may be well to distinguish clearly between national income aspects and balance-of-payments effects. To be sure, the availability or the lack of foreign exchange for specific imports may also, in the final analysis, affect the growth of production and hence of incomes. This latter mechanism, however, is more roundabout than the income effect of exports and of export-related investment, which will be discussed first.

Income Effects of Increased Exports. In an attempt to appraise the scope of income propagation that arises from increased exports, it may be useful to revert to fundamentals. The following brief sketch will therefore be couched in terms akin to traditional multiplier analysis, even though statistical verification could hardly be successfully undertaken. Larger production for export increases the income of an economy's export sector. Higher incomes in the export sector, in turn, tend to bring about a secondary round of income creation, followed by other cycles in the well-known multiplier sequence. Since the marginal propensity to consume is usually quite high in less developed areas, one may feel inclined to expect a multiplier effect of a high order.

In reality, however, a structural peculiarity of underdeveloped economies probably deprives the multiplier of some of its strength. The area in which this mechanism can freely operate is limited to the monetary sector of the economy; the subsistence sector tends to remain outside the main stream of income propagation. Initially, therefore, the cumulative effect of rising incomes in the export sector may not be as large as one would expect on theoretical grounds. By the same token, however, the effectiveness of the multipler mechanism is apt to grow apace with the widening of the market economy and economic development generally.

Still other impediments and leakages hamper the multiplication of income growth originating in the export sector. The narrow productive base of an underdeveloped economy makes for a low elasticity of supply, especially in the short run. Where backward methods and economic organization obstruct the growth of supply in response to greater

demand,[11] a part of the income gain may be frittered away in price rises. Inflationary pressures that result from the rise in exports and its secondary monetary effects thus would tend to reduce the size of the aggregate income gain in real terms.

If, on the other hand, excess demand is met by greater imports, this leakage will also reduce the multiplier. It seems reasonable to assume that the average and the marginal propensities to import are quite high in underdeveloped countries, especially among the high-income groups (particularly if foreign travel and a proclivity to keep balances abroad are taken into consideration). A rapid expansion of incomes would tend to add to this propensity if profits increase more than wages; in that event, a large part of the increment might be spent on luxury imports, while the lower income groups probably concentrate more on domestic staples. To the extent that the distribution of income would thus affect the propensity to import, it matters considerably whether an increase of export values is due to a change in volume or in price. As a rule, a greater export volume brings about an increase in wages and profits, while higher prices raise profits only, at least in the short run. Hence, since profit earners in the less developed countries tend to import more and also to save more, one feels encouraged to speculate that an increase of export prices makes for a smaller multiplier than a growth of export volumes. On the other hand, such savings from higher prices and profits offer greater opportunities for income growth in the long run, depending on the upper income groups' propensity to invest.

Income Effects of Export-related Investment. Since our projections point to a substantial and sustained rise in American imports of numerous commodities, it stands to reason that sizable investments in the producing countries will be required to achieve the requisite growth of output in the foreign producing areas. A large share of the capital will undoubtedly have to be contributed by the industrial countries to whom a large part of the increased output would eventually be shipped. On the other hand, it is believed that the producing countries derive little benefit from such investment because the multiplier effects "took place not where the investment was physically or geographically located but (to the extent that the results of these investments returned directly home) they took place where the investment came from." (H. W. Singer, *loc. cit.*, page 475.)

There is considerable value in this much neglected approach. Nonetheless, it may be useful to probe somewhat deeper. Undoubtedly the multiplier effect of foreign investment is greatly reduced by virtue of the fact that most, if not all, of the equipment is of foreign origin. Thus

[11] See V. K. R. V. Rao, "Investment, Income, and the Multiplier in an Underdeveloped Economy," *Indian Economic Review*, February, 1952, pp. 58 ff.

the import leakage tends to be large; in fact, it may be conceptually permissible to eliminate such "investment in kind" from the investment total and ponder only the income effects of local expenditure. This includes, in all instances, construction and sundry labor and frequently also tools, accessories, working inventories, etc. Moreover, such investments often require collateral investment in transportation, power, and other fields. Experience shows that this local investment component is quite large—no matter whether it is financed from abroad or domestically.

In such a perspective, there is no reason to doubt that this kind of investment is apt to have cumulative effects on income that resemble those of the purely domestic type, provided such investments keep recurring on an increasing scale—as they well might have to in order to produce growing outputs. Moreover, this effect is additional to the previously discussed income-creating effects of increasing export increments.

A related argument appears to refer to the type and localization of investment. It is said that investments in export industries contribute less than other types to knowledge, external economies, and the integration of the economy. (See H. W. Singer, *loc. cit.*, page 475, and comments by Ragnar Nurkse, *Problems of Capital Formation in Underdeveloped Countries* [1953], page 84 ff.) Varying conditions probably tend to make this statement less valid in certain instances than in others. In any event, it does not appear practical to discuss specific investment propositions in terms of alternatives. As a rule, the host country has only the choice of refusing raw material investments or of making the most of the opportunity by demanding a fair share of the proceeds for its own developmental purposes.

Finally, the suggestion that the remittance of investment incomes is an undesirable drain on the host country's capital resources deserves attention. In the event of investments made in order to increase exports to the United States, the foreign exchange aspect can safely be ignored. From any other angle, the important factor for the economic growth of the producing country is not the amount of profits transferred but the amount retained and reinvested. As long as the demand for the product increases—and our projections point in this direction—expansion will be necessary and is apt to be financed from retained earnings. Recent statistics of the Department of Commerce indicate that, lately, the percentage of earnings reinvested by United States companies operating abroad have been quite high, probably upwards of 50 per cent (*Survey of Current Business*, December, 1953, page 10). To be sure, the part of profits that is withdrawn does not directly contribute to the host country's welfare. On the other hand, this is no more

than the price paid for securing the income-raising benefits that actually accrue to the economy from three sources: the original investment, reinvestment of earnings, and increased exports. Although their combined multiplier effect may not be as large as one might expect on abstract grounds, it is likely to be substantially in excess of unity.

Foreign Exchange Aspects. As a country's population and its income grow—owing to increased production for domestic use or for export—more imports are required to match growing needs. Increased domestic production may gradually reduce import requirements of consumer goods, but more capital goods and raw and intermediate materials are needed to promote further development. Therefore, the capacity to import of developing countries has lately received a great deal of attention.

In view of such growing exchange needs, it seems unfortunate that developing countries frequently do not look with favor at increased trade in raw materials as a source of additional foreign exchange receipts. The historic reasons are, of course, well known. They can be summed up under two headings: the danger of overspecialization and the burdens of overdependence. On the other hand, what are the more desirable alternatives to greater exports? Greater foreign investment—even less welcome than trade from the angle of overdependence—cannot be relied upon to increase at a sufficiently steady rate to match the needs. Foreign aid on the requisite scale is even less dependable and much less acceptable to self-reliant nations as a permanent feature. This lack of choice makes it desirable to investigate whether our projections imply a measure of relief from the alleged dangers of increased reliance on exports.

Our projections suggest a fundamental reversal of previously unfavorable trends that had made export specialization appear so perilous. While the possibility of future fluctuations cannot be excluded, their degree and duration will be subject to more effective control by deliberate antideflationary policies in the industrial countries. Moreover, downswings tend to be more moderate in periods of long-term growth, such as those to which all projections point—provided proper policies are adhered to. Furthermore, the prospective shift in the American propensity to import promises to give the full benefit of our rate of growth to our suppliers as a group, though not necessarily to every country. Even more rapid increases of demand are expected elsewhere.(The expected increase of manufactured goods imports by the United States would indirectly increase the exports of raw materials to this country's suppliers.) Finally, as stated before, the terms of trade, too, have already shifted significantly in favor of primary-pro-

ducing countries. On the average, no long-term worsening appears to be in store and further improvement is quite possible.

Producers of products facing favorable demand prospects in this country and elsewhere can thus look forward with greater confidence than ever before to a sustained growth of their export proceeds, provided they can keep in line with cost and productivity trends in their industry. Given such conditions, it is hard to see why they should continue to shrink from promoting the growth of their exports, save for a somewhat amorphous fear of an "overdependence" that is sometimes characterized as "economic colonialism."

Two elements appear to stand out to justify such fears. First, the relative size of the export sector is seen as a structural defect which places the country at the mercy of factors beyond its control. To increase exports would seem to increase the imbalance and make the country still more dependent. Second, the additional foreign investment required to bring about the growth of export facilities seems to enhance the foreign element in countries that strive for greater self-reliance, both financial and hence—as they see it—also political. As a subsidiary consideration, the argument is heard that the export industries drain resources of manpower and skills—perhaps also of capital—that could be used to greater advantage in development projects of a more general nature.

The force of these arguments diminishes if we look beyond the first stage of the growth process. To be sure, both the ratio of exports to total product and of foreign to domestic investment may initially increase when the export sector is expanded. However, as exports grow, the producing country can secure the wherewithal to expand the other sectors of the economy. Deliberate policy in this direction may be needed and has already become commonplace, as the governments of producing countries have proved themselves increasingly adept in exacting a large share of profits and foreign exchange proceeds from exports. If these are used for economic development, the export sector tends to shrink in relative importance, even though it grows in absolute terms. The share of foreign investment also declines as domestic activities increase. (For example, with regard to Mexico see International Bank for Reconstruction and Development, *The Economic Development of Mexico* [1953], page 16 and Table 12, page 183.)

Investment in export industries and in other developmental activities thus need not be considered mutually exclusive alternatives. Each has its function to perform. A growth of export industries is uniquely suited to provide income and foreign exchange with which a progressive diversification of the economy can be financed. In this manner, exports

gradually help reduce the overdependence that they seem to increase in the early stages of development.

The Gains from Trade. Given appropriate policies, the gains from increased exports no longer appear negligible in the light of the preceding analysis. One can occasionally observe a tendency to dismiss these benefits because the prospective average growth of exports appears to be limited to an order of magnitude of 2-3 per cent per annum, or no more than the population increase. It may be useful to evaluate this growth from the point of view of income and of foreign exchange.

Offhand, one fails to see why exports alone should be expected to take care of population growth, and from that angle a reference to population appears irrelevant. On the contrary, one might well wish total incomes to grow faster than exports so that the relative importance of the export sector would gradually decline. What matters for our purpose, however, are two considerations that emerge from the preceding discussion. In the first place, a given increase of exports tends to bring about a proportionately larger increase of incomes. While it may not be advisable to assign specific numerical magnitudes to the three types of multiplier previously referred to, it stands to reason that they are greater than unity, and probably quite substantially so.

Moreover, these increments of income are of great marginal importance. Where exports provide an important share of total incomes and where in the early stages of development such incomes leave little scope for capital formation, the marginal increase supplied by greater exports might over the years make a decisive difference for the future rate of capital formation and development.

Finally, we might be committing a grave omission in viewing the relevance of greater exports only in aggregative terms. From the angle of foreign exchange supplies, the capacity to import specific goods—or the inability to do so—can be much greater than value figures suggest. The history of exchange shortages is replete with instances of desperate attempts to remove bottlenecks by "robbing Peter to pay Paul."

Leaving aside the consequences of improvidence and injudicious policies, the importation of capital goods for development in particular may directly depend upon growing foreign exchange receipts over and above expenditures for essentials. The specificity of capital goods is such that the cumulative output that depends directly and indirectly on the availability of certain equipment is many times its value. In this respect, it may be permissible to suggest the existence of an "equipment multiplier" which expresses the marginal efficiency of foreign exchange increments in terms of productivity of the capital goods they could buy. Although measurement could hardly be attempted, this concept helps

to illustrate the marginal importance of additions to foreign exchange supplies resulting from exports.

To be sure, the benefits individual countries can derive from their exports depend to a large extent on the composition of their foreign trade, their economic structure at home, and their economic policies. In addition, however, traditional mistrust of export activities as an instrument for economic growth often discourages the very development that foreign trade could serve. In the light of the present discussion, one might hope for a more judicious appraisal of the opportunities that a growing export potential can provide under favorable conditions.

DISCUSSION

C. P. KINDLEBERGER: The two papers before us could not be more different. Baldwin is skeptical both of the meaningfulness of the net barter terms of trade and of the possibility of their measurement. He is even dubious that we know what happened to them in 1875. Aubrey on the other hand is prepared to use estimates of population and GNP in 1975 to arrive at forecasts of the volume, price and value of imports, and the price of exports, taking the forecast of the terms of trade fifteen years further into the future than the previous terminal date of 1960.

While my assigned responsibility is to comment on the paper of Baldwin, whom I shall chide for timidity, I cannot refrain from remarking on Aubrey's courage, or should I say audacity. I understand how he arrives at a range for the volume, price, and value of imports—through consulting experts in particular commodity fields, whose biases, if any, are presumably distributed in random fashion and not systematically affected, as were possibly those of the Paley Commission experts in 1951 by short-term commodity shortages brought on by the Korean war. Even here I have difficulty in suppressing doubts as to the ability of these experts to predict the prices of say coffee and cocoa in 1975, the year when I retire, when market forces have had such difficulty in finding stable levels for these goods in the last six months. But the predicted price level of United States manufactures would seem to have an even more tenuous foundation, and with it, the predicted terms of trade. I must leave to my colleagues the task of commenting on Aubrey's views on what these terms of trade imply for primary-producing countries—views which appear to be based on a favorable opinion of income-creation in the process of economic development where I should have thought that no stimulus to employment as such was desirable—and return to the first paper.

Baldwin is of course correct in adopting a skeptical attitude on the meaning to be attached to the terms of trade and to the validity of the statistical record of experience. But does he not go too far? In the case he mentions of trade taking place between two countries where the opportunity-cost ratios between two commodities were identical before trade, I assume that he has in mind trade based on differences in taste. Here the Mill formula based on identical tastes and different production-possibilities curves will not operate, but relatively little change is required to adjust it: the country experiencing the greater change in relative prices before and after trade may be said to receive the greater gain from trade.

When he discusses the welfare implications of terms-of-trade changes, he stacks the deck, in my view, when he claims that it is possible for one country, in a two-country-two-commodity model, with identical tastes and proportionate increases in productivity in both commodities, to experience an unfavorable shift in the terms of trade but receive a greater gain in utility, measured cardinally, than the other. To reach this result, it is necessary to assume that

one country is rich, the other poor, and that the two goods have very different income elasticities. The greater gain in utility for the poorer country experiencing an unfavorable shift in its terms of trade then means only that the utility of material gain for the rich country is smaller than that for the poor. The rich country gets most of the material benefits of the increases in productivity, but since it is sated, it can experience only a small gain in utility. Taussig's point that the change in terms of trade produced by a shift in demand has ambiguity from the point of welfare is of course valid, though I fail to see its relevance to this case with unchanged identical tastes. The gimmick here is that identical tastes are hardly meaningful for countries of widely disparate real incomes consuming at a great distance from one another on the shared indifference map. This is like the equality of the law described by Anatole France which permits rich and poor alike to sleep under bridges on cold nights.

I agree further with Baldwin that it is necessary to make one's welfare assumptions explicit in a discussion of the terms of trade, and that it is useful to discuss much more than the ratio of export to import prices, including from time to time the volume of exports and imports, changes in productivity which may have supervened in old commodities, the effect of introducing new commodities, etc. But while he tells us that it is possible for the terms of trade to move in ways which are meaningless or at least ambiguous for welfare, has he undermined what the underdeveloped countries would want to claim: the existence of a presumption in favor of the proposition that a country is better off as to its balance of payments, its real income, and its welfare, with more rather than less favorable terms of trade. If other things are equal, this is so. And what Singer has claimed, it may be appropriate to recall, is that things are more generally equal in the case of underdeveloped countries than for others because of inflexibility of resource allocation, a slow pace of technological change, etc.

Baldwin's skepticism on the subject of statistics further seems to me excessive. His separate points—the weakness of unit-values, index-number, and sampling difficulties, the bias of qualitative improvement in commodities and the necessity to take into account services as well as merchandise—can all be accepted. Still further qualifications could be added, such as the desirability of correction for the import content of exports, and the unrepresentativeness of single years such as 1938, in a period of cyclical depression, to which many trend measurements run. One can also be skeptical whether the terms of trade improved or declined over given periods of years, although I would think that there was no doubt but that the British terms of trade improved from 1881 (not 1870) to 1913 since the series of Imlah, Schlote, Silverman, and Debenham show a rise of roughly 20 to 25 per cent after an (almost?) equal and much more precipitous decline from 1873 to 1881. The example of statistical ambiguity I prefer relates to the period from the turn of the century to 1913, when the capital outflow from Britain reached its prewar climax. Here year-to-year changes are considerable and, within limits, fairly erratic. Accordingly, one can pick any sort of trend one wants between 1896, 1900, or 1902, on the one hand, and 1910 or 1913, on the other, to claim that

the terms of trade improved, declined, or moved sideways. Certainly no existing statistical measurement of British terms of trade in this period seems sufficiently clear cut to permit economists to generalize about the short-run effects of capital exports on the terms of trade, as many of us have.

One can easily pick disquieting examples of index-number and sampling difficulties especially when the structure of trade is changing drastically. The Staehle example on Belgium-Luxemburg is not very damaging to the cause of index numbers in my judgment since it relates to a year when structural change was under way and covers a seasonal movement which inevitably will produce a spread between the Laspeyres and the Paasche calculations. Statistical crudity makes one wary of attaching meaning to movements of 10 to 15 per cent. There is still likely to be significance to wide movements. Between 1913 and 1952, the net barter terms of trade of Western Europe, according to some measurements I have made, declined 20 per cent vis-á-vis the United States and improved 50 per cent vis-à-vis underdeveloped areas of the world outside of Europe. If the double factoral terms of trade could be measured, I suspect that the spread would have been even wider.

While therefore I agree with Baldwin that their thesis about the terms of trade has been inadequately demonstrated, I am inclined to believe that Singer and Prebisch have given us a penetrating, intuitive insight into the development of the terms of trade in the course of economic growth. Underdeveloped countries tend to produce commodities in which entry is easy and exit difficult. This limits their power to raise prices in periods of firm long-run demand—certainly after a gestation period needed to expand capacity which may be long in such cases as coffee—and to maintain them in depression. Colin Clark, W. Arthur Lewis, and perhaps Aubrey would argue that limits on natural resources are going to change this position with respect to entry as depletion in the United States proceeds and populations grow. They may be right, although the substitution of capital for land in developed economies, whether on the farm or in factories for synthetics, provides a counterbalance of which inadequate notice has perhaps been taken.

As against the underdeveloped country, the more advanced country, provided it is not senescent, can readjust its resources to price changes, so that in the limiting case with Paasche indexes, its terms of trade are always 100. When import prices rise, resources shift into import-competing lines; when increases in demand threaten a rise in export prices, expansion of export volume heads it off. If the supply of export and import-competing goods is more elastic with respect to price changes in developed than in underdeveloped countries and a fortiori if the supply of export and import-competing goods is inelastic for price increases and elastic for decreases in developed countries, elastic for price increases and inelastic for decreases in underdeveloped countries, there may be something to the Singer-Prebisch thesis. But in this circumstance the appropriate therapy is not price stabilization through buffer-stock and similar devices on the demand side so much as increased capacity to adapt supply.

THEODORE MORGAN: The central significance of these two papers seems

to me to be that they each throw light, in two different ways, on a major policy problem: the disposition of underdeveloped countries to identify economic development with industrialization and diversification and to lay their bets for development primarily on manufacturing industries. The very considerable labors of both Aubrey and Baldwin have a healthy effect. They help set up warning signals against the usual acceptance of the British 1876-1948 terms-of-trade data as significant, valid for the world as a whole, and indicative of future trends.

To the extent an underdeveloped country is persuaded by Aubrey's research that primary products will have firm and probably rising prices, it is encouraged to specialize in their production. To the extent it trusts Baldwin's analysis, it would feel that both the significance and accuracy of terms-of-trade data of the past are questionable.

The basic procedure used in the Aubrey study is to resort to commodity experts for guidance. Imports are the difference between domestic capacity production, allowing for technical advance, and domestic consumption, as estimated. Prices are a "partly intuitive but [to the experts] quite tangible, appraisal of long-run cost trends in their industries." Population is projected, as basis for demand for food, despite lamentable experience in population forecasts.

Certainly these estimates are extremely fragile. The experts are asked to estimate imports as a residual, in the darkness of twenty years ahead, allowing for the unpredictable gifts of technology!

But it is not fair to Mr. Aubrey to emphasize overmuch the extreme precariousness of long-range predicting. The fact is that no method is much good. At the same time, estimates are in perennial demand. The aim is to do the best one can.

By this modest standard, Aubrey's method looks worth trying. One can allow for experts' tending to be conservative in their projections ("better to fail conventionally than to succeed unconventionally") and for their probably being overinfluenced by the experience and trends of their recent past, and still come out with the feeling that predictions of the future that diverge drastically from this consensus-of-experts view at least need strong support.

What about the income effects of increased exports from underdeveloped areas? The discussion implies—or I misread it—that rising money incomes are an advantage. But they are mixed: partly a problem, partly an opportunity. There may result some modest rise in domestic production, which is desirable. There will tend to be rising domestic prices, beyond a moderate level undesirable. There will tend to be a sharp rise in imports of consumer goods. The government's problem is to capture a large share of the windfall increase in incomes and divert it to long-run investment. The early discussion here omits government and so omits the crucial government problem of devising a tax program to minimize the problem and maximize the opportunity.

With respect to Baldwin's paper, the case, I think, is not proved on the major issue of what terms of trade are least objectionable toward indicating the effect of foreign trade on real income. Of his three indexes, he concludes "the commodity terms of trade appear to be among the most objectionable."

But the only criticisms are that an increase in the productivity of resources used for exports can more than offset a deterioration in the terms of trade and that long-run benefits can sometimes more than compensate for short-run injury. These are reasonable qualifications. If they are not taken into account, that seems the fault of the user, not of the index.

The comparative advantage of the commodity terms-of-trade index receives further evidence from the neat illustration that Baldwin gives of how the income terms-of-trade index (total value of exports divided by an index of import prices) can easily go astray.

The third index is the single factoral terms of trade: the commodity terms of trade multiplied by an index of the productivity of the factors of production. This is statistically unusable save for the single factor, labor, which is at best only one of several factors.

Nor is the solution of using a lot of data—"export and import volume indices, productivity changes in the export and internal sectors, and a host of other economic indicators"—generally useful. Nearly all underdeveloped countries, and many developed ones, just do not have a lot of reliable data. And ordinarily the time and funds of the investigator are limited, and he is forced to look to one or several of the most significant kinds of reliable data available.

I am forced to the view that Baldwin's analysis leaves his reject single measure, the commodity (or perhaps commodity plus services) terms of trade, still in first place.

Next, to the data. Some problems of construction of terms of trade simply blur the result. The general weighting problem is an example. But the biases usually found tend consistently to understate the price position of the primary producer. The new products and quality change bias mentioned by Baldwin both tend to understate the relative price position of primary producers, since improvements have taken place predominantly in manufactures. Again, the British data, measuring value of exports and imports at port of entry or exit, have a built-in distortion that further understates the relative price position of primary producers—for as Baldwin illustrates, transport costs have been falling in the past century. More and primary-producing countries have been paying a price for British goods higher than British export prices by a falling margin; and primary producers have been getting paid a rising proportion of the prices of their products valued at British port of entry.

And further still, the Schlote data for Britain, 1801-76, show a very wide improvement in the relative prices of primary products—so wide as to leave no room for doubt as to the trend.

These indications of weakness in the British data quoted from the League of Nations and UN studies have led me to investigate customs and domestic data on the relative prices of primary goods versus manufactures in six other countries for which data appeared reliable enough to use. The countries were the United States, India, Japan, New Zealand, the Union of South Africa, and Brazil. Data from two countries went back to the beginning of the nineteenth century, three to the 1860's or 1870's, and two to 1901 and 1910.

The results show much variety of experience. Two countries show clear rises

in the terms of trade of primary producers (the rise in the United States is remarkable—some 400 per cent since the beginning of the nineteenth century, on the basis of excellent data); four show various changes or ambiguity. With these results can be compared a recent (September 15, 1954) Pan American Union study of the terms of trade of all Latin America. The recent level is found to be about the same as at the beginning of the century.

I conclude the British data are misleading. There has not been any general worsening of the price position of primary producers.

Should we expect such a worsening? Prebisch said yes on the ground that "lack of organization among the workers employed in primary production prevents them from obtaining wage increases (in the boom) comparable to those of the industrial countries and from maintaining the increases to the same extent (in depression)." (*Economic Development of Latin America,* page 13.) Singer said yes since "technical progress in manufacturing industries showed a rise in incomes while technical progress in the production of food and raw materials in underdeveloped countries showed a fall in prices." (AEA *Papers and Proceedings,* May, 1950, page 478.) Kindleberger said yes in his *Dollar Scarcity* (page 122): "The certainty of loss arises for agricultural and primary product countries from the assumption of continuously increasing efficiency of production in these and in manufactured products, and . . . the application in these circumstances of Engel's law." Today Kindleberger is inclined to say yes because of assumed supply elasticities in developed and underdeveloped countries.

Here are four lines of explanation for a fact that is at best questionable. What if the terms of trade of primary products have not been worsening? The general doubt associated with these arguments seems to me to be that they look to matters associated with and derivative from the trend of prices of primary and manufactured commodities rather than to the basic determinants of those prices; that is, the long-run trends of world supply and demand. I suggest that on these basic determinants it is possible to say something, despite scarce data.

ARNOLD C. HARBERGER: Let me announce at the outset my admiration for Mr. Aubrey's bold spirit. Though one may quarrel with the details of his paper and his approach, one cannot help but sense that he is grappling with real and important problems and doing so with great imagination and competence. More cautious minds would shrink from the task which Mr. Aubrey has set himself, but I do not hesitate to assert that our knowledge would advance much more slowly if caution became our byword and the sureness of our conclusions our major goal.

It should be clear, then, that I do not want to carp at small details in Aubrey's analysis. I rather want to point out two major crossroads at which he may have taken the wrong turn. The first concerns his use of a commodity-by-commodity approach in assessing the probable future course of the primary-finished terms of trade. The second concerns his emphasis on the possible multiplier effects of investment in underdeveloped countries.

One cannot be long immersed in the data on long-term growth and develop-

ment before realizing the tremendous role played by technological advance. The great surges of development which our country and others have enjoyed cannot be explained on the basis of the observed increases in the working force and the stock of capital. Half or more than half of our secular growth in output seems to stem from other causes, which I tend to lump rather indiscriminately under the heading of technology. Unfortunately, we know precious little about the forces which govern the rate of technological advance. We rest, in making long-term projections, on the average pace of such advance in the last half century or so, and we treat this rate of advance as a sort of statistical regularity. While regretting its necessity, I do not object to the use of so crude a procedure in taking our sights on the future. However, I do feel that we must keep firmly in mind two facts that can easily be gleaned from existing data: our technological advance has not been at an even pace, but has come rather in fits and starts; even over long periods, there have been wide divergences in the average rates of technological advance enjoyed by different industries. These facts suggest that our crude assumptions are at their best when we deal with rather long periods of time (to average out periods of spurt and sluggishness) and with rather broad commodity groups (to average out individually divergent rates of progress).

One may here ask whether Aubrey is not on safe ground in making independent projections of the relative prices of a series of primary commodities, and then averaging out the results to get an index for the group. Here, I think, we must inquire more closely into the precise method he used. Demand projections, obtained by familiar and relatively widely accepted methods, were juxtaposed to supply projections based in a consensus of expert opinion. Price projections were deduced, again with the aid of expert consensus, from the size of the anticipated gap between supply and demand at recent prices and from the anticipated responsiveness of both supply and demand to price changes. Now I have the utmost respect for the judgments of commodity experts in the daily decisions they have to make. Yet I wonder whether these experts could have been sufficiently indoctrinated in the subtleties of secular growth to give predictions that are reliable for the long run. If we think in terms of a constant price level, we can envision labor costing roughly double its present wage a quarter century hence. In some commodities, technological advance will have operated to make labor three or four times as productive, so those commodities will decline in price. Other goods will have been more or less bypassed by the surge of technology and they will suffer price rises. It seems to me that few experts could be expected to give reliable judgments as to the likelihood and impact of major innovations over the next twenty-five years. Yet do not their price projections imply just such judgments? My feeling here is that these implications were seen only vaguely, if at all, by most of the experts, and that their projections ignore to a great extent the crucial technological elements in economic progress.

All this might be of minor importance if Aubrey's general conclusion were supported by an analysis of the primary-finished terms of trade on a more aggregative level. But it is not at all clear that this is so. I shall confine myself here to presenting a plausible picture of the world a generation from now, in which, contrary to Aubrey's expectation, the terms of trade have

moved against primary products. I make no pretense of its being more than a rough sketch, and I emphasize that I do not rule out the possibility of an equally plausible case being made on the other side. I only hope to preserve the future of the terms of trade as an open question for further speculation and analysis.

Assume for a moment that the population of the world remains stable and that, due to technological advance and related forces, output per head doubles in a generation or so. Let this doubling of productivity occur in both the developed countries and the presently underdeveloped ones and in both primary and finished goods production. It is well established that the income elasticity of demand for primary products is well below unity, and I think we can safely assume it to be somewhere around .5. Under the assumed conditions, market forces a generation hence would call for a net movement of one-fourth of the resources presently in primary production out of the primary and into the finished goods sector. This is a movement of substantial magnitude, and it probably would be impeded by the usual barriers to mobility. Yet if the movement were not accomplished, primary product prices would fall relative to finished goods prices; indeed, such a fall would appear to be the market's way of calling forth the needed movement.

Now let us relax the assumption of stable populations and assume that the population of primary-producing areas increases more rapidly than that in the rest of the world. This, clearly, would only accentuate the downward pressure on primary product prices. To reach Aubrey's conclusion we must assume either a rather strong bias in technological advance against primary products or a rise of limitational factors (ore reserves, land, etc.) to a place of almost unprecedented importance.

My second point has to do with Aubrey's use of a multiplier-type analysis to assess the effects of increased exports and export-related investment in underdeveloped economies. Multiplier analysis is at best with problems of cyclical unemployment. Here, owing to a number of rigidities in the price mechanism, it is usually reasonable to view increments in output as if they had no cost in terms of foregone alternatives. Secular analysis typically—and I think properly—assumes resources to be fully utilized. A rise in the price of exports then enhances the real income of the exporting country just as a rise in a person's wage enhances his real income. An increment of capital adds to the output of a country its marginal productivity. One needs, I think, more justification than Aubrey offers before one abandons this traditional picture. One can go a part of the distance by assuming that disguised unemployment is rife in the less developed countries, with labor in particular having effectively zero marginal product in many areas. But I feel that disguised unemployment of this type is the special rather than the general case. Almost by definition, it cannot exist in a market economy, and to the extent it has survived in a nonmarket sector, resisting the blandishments of a going wage in the market economy, special explanations, varying from place to place, will probably be required. In particular, there is no reason to expect that such disguised unemployment, rooted in custom and tradition, would be dissipated through the workings of a Keynesian multiplier or an export or investment base.

ECONOMIC RESEARCH AND PUBLIC POLICY

By J. A. Livingston
Philadelphia Bulletin

To prepare this paper, I sent out a questionnaire to seventy-six economists and statisticians and received replies from twenty-five. Among the respondents was Robert R. Nathan, who started off by saying: "You are a lazy bum making others work for you. However, you have done that successfully in the past and I don't blame you for continuing."

Another of my unpaid advisers was J. Frederic Dewhurst, who declared: "You deserve the title of Mr. Questionnaire, not only because of the headache you send out every six months, but because of your circular letter. Are you trying to get everybody else to write this paper for you?"

Both Nathan and Dewhurst referred to my custom of collecting semiannual forecasts from fifty to sixty economists. The result of those questionnaires led me to the conclusion two years ago that economic forecasters are wrong about two times out of three. Since then, I have revised my faith upward. The economists have been remarkably accurate in anticipating the 1953-54 recession and recovery. The record has so improved that I can now say that economists are right about half of the time. Since business can move up, down, or sidewise, this is reasonably good. There are two chances out of three to be wrong. Hence, a fifty-fifty record is better than chance.

This forecasting record is cited because of its relevance to our subject. In a society in which the government assumes responsibility for economic stability and high employment, forecasting becomes a part of the public domain. National policy cannot be made without some assumptions about the future. And the hazards of forecasting will be reduced if the government achieves economic stability. The less erratic is the business cycle, the less eratic will be forecasting. That will set off a nice chicken-and-egg argument: Did accurate forecasting produce economic stability or economic stability accurate forecasting? And it is desirable for the government to adopt measures which lessen dependence on forecasting. Of this, more later.

We are in a new era. It began with the Employment Act of 1946, which established a Council of Economic Advisers to assist and guide the President in formulating his economic program. It established in

the Congress a Joint Committee on the Economic Report, which studies proposals of the President, and then suggests implementary[1] legislation. As the result of the law and the Great Depression of the thirties which foreran the law, the American people expect the government to prevent depressions—to protect them against protracted economic disuse and disability.

Forecasting is unavoidable because administrative wheels grind slowly. It takes three to six months to wind a tax bill through Congress. It takes as many months to put through appropriations. Changes in defense schedules likewise are authorized by the various committees slowly. And, if Congress closes its doors in July or August and the economy needs legislative treatment in October or November, it is just too bad.

Only an emergency would induce a President to call a special session. That is politically possible if business is in a tailspin, if unemployment is developing rapidly, bankruptcies rising, and the stock market falling. The needs of the times would communicate to the President and Congress what had to be done. It is much less likely that the President would call a special session to combat inflation—if higher taxes were needed, say, to check a roaring excursion into overfull employment and a price boom which might ultimately degenerate into a business bust.[2]

Therefore, the President and his advisers and the Joint Committee on the Economic Report must formulate judgments on what is likely to happen long in advance—as much as a year—so as to be prepared for countercyclical action. This country was fortunate in the 1953-54 recession. Some tax reductions became law, in line with President Eisenhower's recommendations and others in spite of his initial resistance. These imparted an uptow to consumer income and business profits which helped to moderate the decline.

I directed the questionnaire to economists accustomed to forecasting. They are familiar with its hazards, frustrations, and necessity. They have been willing over the years to subject their judgment to the harsh caprice of actual event. I wanted to find out from them what, if

[1] The Committee itself does not initiate legislation. But members of the Committee are on various legislative committees of Congress and so are in a position to influence fiscal, monetary, farm, and other legislation.

[2] I realize that in the summer of 1948, President Truman, after his nomination for President, called a special session of the 80th Congress for legislation on selective price, materials, rationing controls, stronger rent controls, and an excess profits tax. Congress went through perfunctory motions of heeding the President's requests. No legislation resulted. Mr. Truman's action was regarded as a political maneuver to put the Republican Congress on the spot. Inflation is never entirely displeasing. It was not displeasing in 1948. Furthermore, there were signs—notably falling farm prices and leveling off in the consumers' price index —that inflation was not as great a worry as the President said it was. In fact, Christmas business sloughed off and a recession developed in 1949.

any, additional information would make forecasting more scientific—would make them feel more confident of their predictions. I wanted a generalized judgment of the nation's statistical and research needs.

To be sure, the Subcommittee on Economic Statistics of the Joint Committee on the Economic Report conducted hearings on this subject in July. Well-known economists from government, business, universities, and research organizations appeared. They mentioned the missing weapons in our statistical armory. They commented on the need for greater detail in some series and for greater speed in others. They discussed the pros and cons of speed versus accuracy.

But at no point did economists and statisticians, as a group, submit an order of priority. What data are they most anxious to have? It was this gap I hoped my questionnaire would fill. It has done that only partially.

The answers indicate the concerns of the moment. When the next slump comes, if it comes, we shall be able to determine whether economists have been concerned about the wrong things. "The future is only the past again, entered through another gate," said Paula, in the closing line of Sir Arthur Wing Pinero's *The Second Mrs. Tanqueray.* In economics, however, the past offers so many gates that it is all too easy to enter the wrong one.

There was unanimous accord among the respondents—implied or specific—that the government has the responsibility to provide regular censuses of population, manufactures, business, and agriculture. These are absolute musts—benchmarks for our understanding of the world we live in. Schedules should be regular, uninterrupted by budgetary ups and downs. This reconfirms the recent findings of the Intensive Review Committee appointed by the Secretary of Commerce to evaluate the work of the Bureau of the Census.

Beyond that, the comments indicated that economists and statisticians expect the government to continue its collection of basic statistics, such as employment and unemployment, consumers' prices, wholesale prices, housing starts, banking data, new orders, sales and inventories, consumer expectations, and so on. There was not a single suggestion for curtailment. But there were several suggestions that in forecasting—in analyzing probabilities in business—statistics as statistics can be overemphasized. "We don't need more data," said one respondent, "we need better judgment."

My first question was: "What are the most important gaps in our statistical information which prevent or hinder the federal government in making effective policy decisions to maintain economic stability? (Your answer might well cover data which are seriously lacking or seriously deficient in quality.)"

Forty different types of statistics were mentioned. One economist expressed a desire for more information on industrial accidents; another for more frequent data on the gross national product in constant dollars; another for information on the costs of doing business; another for additional seasonally adjusted data on federal receipts and expenditures; two for information on the number of unemployed persons not receiving unemployment benefits; another for better information on farm expenditures; another recommended the accumulation of regional information.

Two demands stood out. Ten economists asked for better information on construction. Among the specific points covered were: more information on the supply and demand for new homes; more complete information on vacancies and conversion and demolition of old dwelling units; general improvement of all data.

One respondent said: "Additional data on real estate market developments might be of strategic importance in the next few years." Another economist was less oracular. He said: "The great construction boom of the twenties aggravated the collapse of the thirties. What about the soundness of the present building boom? Judged by the needs of the entire business cycle—not just the boom phase—are we overbuilding temporarily? And, if so, is not the government with its credit policy more responsible than anyone else? These are matters we know too little about."

Seven requested more detailed data on new orders, sales, and inventories. Oliver P. Wheeler, of the Federal Reserve Bank of San Francisco, commented: "The key role which inventories play in most short business cycles and often in major cycles, seems to call for more 'disaggregation' in the study of the inventory cycle."

There were requests for more data on consumer spending, savings, and intentions to spend or save. There were, also, requests for information on businessmen's expectations. Three economists asked for improvement in the BLS indexes of productivity.

The second question was: "What do you think the government's role should be in economic research? Should it engage solely in gathering of statistics on current developments or should it engage in long-term research projects on the effects of government policy on the economy? (This last type of research has usually been done by private organizations, such as the Twentieth Century Fund, National Bureau of Economic Research, etc.)"

Fourteen of the respondents felt that the government should engage in long-term research. Usually, the feeling was positive and enthusiastic. Six objected. The principal objection was that the government would not be impartial, that the research would be politically moti-

vated. Five did not answer the question.

The third question was: "What economic policies followed by the government in the past year do you consider most open to criticism? Would better statistical data or research have pointed out beforehand the shortcomings of these policies?"

The economists seemed to divide into two groups. Those who might be described as of the New Deal-Fair Deal school felt that the tightening of money rates was a mistake. They felt that the government should have taken more positive steps when defense expenditures were tapered downward. The increase in unemployment would not then have occurred and should not have been countenanced. Economists associated with labor unions or with labor ties were emphatic in this latter view. They expressed the feeling that the government has the responsibility of maintaining an ever expanding economy. There is no need for layoffs, letdowns, and unnegotiated shorter work weeks.

On the other hand, economists associated with banks or business firms felt that the present administration had done all right. This group is not nearly so united in its thinking as the New Deal-Fair Deal group. It is opposed to the policy of keeping the economy in perpetual high gear, ever expanding. Constant government ministration to maintain expansion would only lead to inflationary boom and then to a bust. One respondent said: "What this country needs is more frequent and milder recessions." Some in this group questioned the easy-money policy. One said that after tightening credit the administration loosened up too soon. Yet there was even some criticism of the hard-money policy in early 1953, which indicated the lack of agreement.

The fourth question was: "What economic policies would you recommend at this time? (In your answer, please indicate any important assumptions you are making about the economic climate during 1955.) Do you think that additional data or information now available would give you firmer convictions about the policies to be pursued? If so, what information would you need?"

The eighteen answers to this question produced a standoff. Nine respondents felt that the government ought to give the economy an upward push—by spending on roads, public works, defense, or by reducing taxes. Nine others felt that the present administration's policies were fine, that no great federal exertions are required, that an upturn is at hand. Immediate and large injections of government spending are unnecessary.

One respondent said the principal problem was to guard against overspeculation; another said the principal objective should be to stop inflation. Here, the inference is that the easy-money policy is leading to excessive expansion of home building and construction of all kinds.

As investment funds seek outlets, they may go into projects which are not too well planned and which, eventually, will lead to business failures and overcapacity—redundant and competing shopping centers, for instance.

There were no positive expressions of what additional information would have led to firmer convictions about policies to be pursued.

I believe the response to the questionnaire indicates that economists feel the government must assume responsibility for providing statistics and research necessary to decision making, both public and private, in order to "promote maximum employment, production, and purchasing power."

Yes, private research should be encouraged. The federal government ought not to try to take over all statistic gathering and research. When trade associations and industries gather facts, fine. But if it happens that an important segment of industry is "unguarded," then the federal government must gather the information. The cost of gathering information is small relative to the cost of unemployment and the psychological shock of a swift, sudden decline.

The 1937-38 slump is a case in point. Had we known more about sales, new orders, and inventories, perhaps we would have been wise enough to have prevented the economic heartache. In 1936 and in 1937, the Federal Reserve Board raised reserve requirements and tightened credit when industry was running out of new business. At the time, we had virtually no satisfactory data on new orders, sales, or inventories. It is possible that government policy aggravated the 1937-38 readjustment—one of the sharpest and swiftest on record. Immediately after the drop, many agencies—the National Industrial Conference Board, private research organizations, and the Department of Commerce—decided to plug the gap. Information on new orders, sales, and inventories was the statistical rage!

The answers to my questionnaire are significant in this regard. The emphasis on better construction and housing data and the emphasis on new orders, sales, and inventories hark back to the two most recent and important slumps: the Great Depression of the thirties, in which the falling off in new housing was one precursor, and the slump of 1937-38. These emphases are understandable. Men remember what hurt or fooled them most recently. This is the stable-door method of preventing depressions. You close the statistical gap of the last depression.

We cannot neglect the indicators, the barometers, which might have given us foresight in previous declines, but neither dare we assume that the causes of earlier depressions will repeat themselves in the same

ways. In a changing economy, men's excesses, which cause slumps, take new forms. Economists and statisticians—particularly those in government—must be ever alert to changes in the character of the economy and statistics so as not to be beguiled.

We all know how statistics lose their meaning. Once, carloadings was considered a significant indicator of business conditions. But during the twenties freight cars became larger. Carloadings did not reflect the increase in traffic of the period. Just when we became adjusted to this shift—we allowed for the increased tonnage per car—the truck became an important freight mover. Carloadings then declined, not only because cars were more capacious, but also because freight was moving over highways instead of rails.

Consider pig iron. The stock market used to rise and fall with it. Now it is obsolete. Steel has taken over as the nation's work-horse metal. Yet even this is changing. Steel is not so dominant in metalworking as it once was. Aluminum is up and coming. Once we reckoned aluminum in pounds. Now it is a tonnage metal. And it is used in operations which usually require more machine-hours than steel—in airplanes and airplane parts, for example. As aluminum increases in importance, steel may decline in importance as a statistical guidepost.

Business failures are another indicator which may be undergoing a change. This is the era of the large corporation. Business firms have branches in many places. The small family-owned firm represents a decreasing percentage of total assets. And since the small firms are more likely to fail than the large firms, business failures may be less sensitive as an indicator of economic change than formerly.

Let me try to illustrate this. You have probably read that John Wanamaker's has closed its New York store; that Alexander Smith & Sons, carpet manufacturers, is shutting its Yonkers plant, which was built during the Civil War; that Gotham Hosiery has abandoned its knitting mill in Philadelphia; that International Shoe shut a plant in Manchester, N.H. In the twenties, each of these plants would have been a corporation or a company by itself. Each closing would have entered the bankruptcy or business-failure totals. And as a result of such shutdowns, creditors would have uncollectible accounts. That is not so today.

These are business failures of a type. An establishment is outmoded. Trade has passed it by. Equipment is inefficient and obsolete. A bigger plant has been erected by the parent company elsewhere. But no bad debts result. The parent company is still solvent. Yet the local area is directly affected. An employer is moving away. Disemployed workers will have to find jobs in other companies in the area or move away. Personal distress—nonpayment of bills or defaults on mortgages

—will result. The local impacts are pretty much the same. Yet the failure at the local level does not register in the business failure statistics.

We know more than we ever did about what makes our economy tick. We have more statistics, more information, better-trained statisticians and economists, and better mechanical equipment. But we also have a far more complex economy with which to deal. And we know that economists differ on when and how to cope with inflation and deflation. If we knew, really knew, there could be no difference of opinion. We know some facts, but not all the facts. Hence we interpret the facts we know differently. When all the facts about a problem are on the table, the answer dictates itself.

Not only do differences develop about how to achieve maximum production and employment, but differences develop over the methods for detecting changes in the level and "quality" of business. Some economists study the behavior of business indicators, such as business failures, steel operations, new orders, sensitive commodity prices, new incorporations, paper board production, lumber production, housing starts, and so on. By analyzing each series, they hope to detect declines or upturns in business early enough to permit government action to prevent either inflation or deflation. And among this group, there are differences over the relative importance of the so-called "barometers."

Another school of economists relies on models—economic models, not Conover or Powers models. Attempts are made to estimate the gross national product by making projections. These projections are aided by data which possess a "forward look," such as the SEC-Commerce compilations on plant and equipment expenditures by industry, the University of Michigan studies of consumer-spending plans, and so on. Sure, the parts of the economy are interrelated and the forward-look components help to indicate direction and total expansion or contraction. But here again the accuracy depends on the assumptions the model builder makes and on the reliability of the forward-looking data. Sometimes estimates based on surveys turn out like the election polls.

Federal budget estimates, which ought to be dependable, have been off the target—even over comparatively short terms. As one recent example, in January, 1954, the government estimated that tax receipts in the fiscal year starting July 1, 1954, and ending June 30, 1955, would amount to 62.7 billion dollars. But by September, 1954, the estimate was lowered 5 per cent, to 59.3 billion. That change, of course, could be attributed to events not fully anticipated—to changes in business conditions and the tax law.

The government did not do too well in its estimates of its own ex-

penditures, either. In January, 1954, the estimate of spending for the 1955 fiscal year was 65.6 billions; in September, only nine months later, that was revised downward by 1.6 to 64 billion which is not too bad. But we do not know what the actual results will be by the time June, 1955, rolls around. In this instance, the forecast of reductions in tax receipts and expenditures is partly offsetting. The errors almost canceled one another.

But errors can be self-reinforcing instead of counterbalancing. Then the model goes way off. This is its nature. An assumption in one sector of the economy often influences assumptions in other sectors. As an instance, if you estimate that government outlays on defense will drop, you might also assume that consumer purchases will drop because of resulting unemployment. This partially explains the forecast of eight million unemployed in 1945 and 1946. The economists in the Office of War Mobilization and Reconversion knew government outlays would drop. But they underestimated the speed with which industry would reconvert; hence they overestimated disemployment and underestimated payrolls. As a result, low estimates of consumption, production, and employment were all in the same direction.

Each economist is bound to have his own predilections—his own methods—in trying to forecast business changes and in trying to formulate government policy to abet a high level of employment and a rising standard of living. I do not believe that the government can afford to rely solely on the barometric approach or model building for forecasting. Both are necessary.

Furthermore, in the effort to determine what action the government must take to influence the course of business, a model is essential. Both the analyst and the policy-maker want to know whether construction needs bolstering, or consumer purchasing, or business outlays. The model suggests areas in which government support is needed to achieve a high-level employment.

The model builder is like Professor Higgins[3] in Shaw's *Pygmalion*. Just as the Professor tried to correct and recorrect Eliza Doolittle's speech so that she could pass as a lady, the economist builds a model of what is likely to be. Then he recasts it—according to his conception of perfection. Government policy then is directed to obtaining this ideal. If the policy is correct and successful, the resultant model, like Eliza, is the modeler's dream.

Under the Employment Act, the government must engage in constant business cycle analysis. The Council of Economic Advisers takes

[3] Not to be confused with Benjamin Higgins, author of *What Do Economists Know*, a charming, clarifying set of five lectures.

the lead in this, assisted by the many research and statistical agencies of government, the Department of Commerce, Bureau of the Census, Federal Reserve System, Bureau of Labor Statistics, and so on. This has immediate application to current business conditions and fiscal policy.

But government must not stop there. I think it ought to undertake —directly or through private research organizations—studies into long-term economic trends or contingencies. I have in mind studies such as the Paley report on America's resources. We have to review periodically the long-term prospects for supplies of basic commodities, such as petroleum, iron ore, copper, aluminum, and so on, to determine our competitive position vis-à-vis the rest of the world. We talk about the possibility of becoming a have-not nation. We must also study the dangers of becoming a high-cost nation.

Likewise, it is desirable for the government to continuously examine the economic consequences of postwar technological improvements, of automation. Are we on the threshold of a great expansion in output per man which will make the forty-hour week obsolete? Will that result in large-scale unemployment and an economic crisis? Or will the labor unions exert countervailing power on industry and obtain reductions in worktime at rising hourly rates to offset increases in productivity?

The government might also want to make continuing studies of consequences of the great flow of savings into savings institutions. Raymond Goldsmith has worked on phases of this problem. Will insurance companies, savings banks, and other institutions be so pressed to invest funds that they will become parties to industrial and commercial overexpansion?

We have to keep abreast of the effects of an aging population on production and consumption and the tax burden on the younger population. We also will want to study the impact on the economy of the increase in babies. In the next ten years, will we need more schools, factories making children's clothes, etc.? Not only does gross population have an impact on business, but so do its segments. In our emphasis on the aged, on geriatrics, we must not forget the economic influence of the younger generation.

Government fiscal policy, itself, calls for special long-term research. We have certain theories about the effect of taxation on consumption and investment decisions. But are they justified? Do high corporation taxes, for example, discourage business investment? Or does business merely pass along the taxes to the consumer and, for purposes of reinvestable funds, hold back earnings from stockholders?

Similarly, it would be well to re-examine the effect monetary policy

has on the business cycle. We assume easy money encourages businessmen to borrow and to expand and that high interest rates have the opposite effect. How valid is that?

Another long-term research project would be the relationship of the farm and urban populations. The government has to support farm prices today because of surpluses. But is it possible that the increase in mouths to feed and bodies to clothe in the decade ahead will result in an enlarged demand for foods and fibers, thus increasing the economic bargaining power of the declining number of persons who remain on the farm? Is the farmer moving into a new strategic position—from political to economic strength?

Other subjects which might come under the government's purview are the expansion in state and local debt. In the next five or ten years, the burdens assumed by states, cities, and towns in providing hospital, school, road, police, and fire services could create a taxpayer crisis. Could they also cause a financial crisis?

I also think that the sale of revenue bonds—for the building of roads, schools, and other civic improvements—is a source of potential financial danger. We are creating in the United States state-sponsored enterprises which have the benefit of tax exemption. Yet the service of these bonds—the payment of interest and the building of sinking funds—depends entirely on income. If for any reason a road is poorly planned, the bonds would default. Is this device abused? And could it result in a loss of faith in municipal and state credit?

Long-term research has this advantage over short-run analysis. It lifts minds and imaginations out of day-to-day detail. Secular changes are observed. New economic probabilities can be dreamed of in the freedom of not trying to find solutions to immediate problems. The present is better understood for knowing the past and peering starry-eyed into the future.

At the outset, I alluded to the difficulties of forecasting, yet the necessity for it. If a business decline occurs when Congress is out of session, it would be months before Congress could act—even assuming the President were to call a special session. Therefore, it would be well for us to introduce greater automation and flexibility into our anti-depression armory so as to depend less on prophecy.

We have certain flexibilities now. The graduated income tax is a negative form of flexibility. As personal incomes drop, the burden of taxation falls. Similarly, as corporation earnings decline, the corporate tax burden is reduced. The government shares about half the drop in pretax income. Such automatic reductions in taxes cushion the severity of the business decline. But they do not increase income. They are not contracyclical in effect.

Unemployment compensation also is automatic in response to a recession. Workers are laid off. Their incomes do not collapse. Old age pension payments also come into play. Persons who are entitled to pensions who lose jobs can draw on their pensions after unemployment compensation is used up. Thus we have automatic income-supporting measures.

But what if these are not enough? What if the decline proceeds rapidly?

We ought to give serious consideration to empowering the President—or the President in consultation with a Congressional committee—to take positive action to lift income when Congress is out of session. For example, we talk of the need for a continuing shelf of public works—to be spread around the country when unemployment rises. But building highways, constructing public buildings, dredging rivers, and expanding research all require funds. Ought we to set up a special reserve fund of two to five billion dollars to be used by the President at his discretion or on some automatic signal, say, when unemployment reaches five million. (Herbert Stein, of the Committee for Economic Development, has gone into economic automation in great detail.)

Similarly, should the President have standby power to reduce the tax rate in the lowest income bracket, so as to immediately increase the amount of income available to persons who have jobs and whose incomes have not been reduced? Should he be permitted to cut certain excise taxes? These actions would be contracyclical in effect.

Congress is always reluctant to give the Chief Executive discretionary authority. (Probably it will take a crisis to jar Congress loose from this reluctance.) Congress might be more receptive to this idea if some Congressional strings were attached. Suppose a small, special, standby committee were established to act with the President if an emergency develops while Congress is out of session. This committee might consist of the majority and minority leaders of the House and the Senate, the two ranking members of both parties on the two Appropriations Committees, the House Ways and Means Committee, the Senate Finance Committee, and the two Banking and Currency Committees, and the Chairman of the Joint Committee on the Economic Report.

The methods for dealing with a recession would already have been set up. What would then remain to be determined by the President—or by the President and a Congressional committee—is the timing: when to put the measures in force. And a time limit should be established on tax reductions. The rates should automatically be restored at the end of a year—unless Congress legislates to the contrary in the meantime. (I am not suggesting an automatic anti-inflation program. That would require raising tax rates. I hardly think Congress would

grant the President or a committee power to notch taxes up—even within limits.)

The purpose of an automatic antideflation program is self-explanatory: to anticipate unanticipated changes in business conditions. It would be a stopgap, pending the convening of Congress and the enactment of formal legislation to meet the specific problems. It would take the burden off the Council of Economic Advisers to forecast correctly six months to a year ahead.

I have one further point to make on economic research and public policy. I propose a new agency—a private agency—to be the private counterpart of the President's Council of Economic Advisers. I think it ought to be financed by a foundation, such as the Rockefeller, Ford, or some other organization interested in the social sciences. It would report to the public at large. Its function would be to analyze economic trends just as does the President's Council. It would appraise the Council's report to the President, the President's report to Congress, the policies recommended by the President, and the economic effects of Congressional legislation. This private council of economic advisers would have the responsibility of analyzing public statements of government officials—the President, the Secretary of the Treasury, the Secretary of Commerce, and so on—to determine their validity.

Such an independent research organization is necessary because of the institutional character of government research and government policies. Within government, there is freedom to criticize and argue. But once an executive determination is reached, once a policy has been set, the critic, if he is to remain in government service, is silenced. He must then become a conformist. He must be on the team. In this, government is no different from a corporation.

This institutionalization of attitudes within government has dangers. Take a simple example. A budget is developed. It calls for a certain level of taxes and outlays. It is argued back and forth. Finally, it is adopted. Some government economists may feel that expenditures are greatly overstated—that the Department of Defense may not be able to let contracts as rapidly as the budget implies. That being the case, the income-supporting implications of the budget are exaggerated. Therefore, they feel that the Council of Economic Advisers, the Department of Commerce, and other government agencies should discount the budget.

But here is an authoritative document. It is the President's final word on income and outgo. How can government economists argue with *the word?* Department of Commerce or Department of Labor economists cannot make brash statements about the budget being unrealizable. They have to accept it. Most persons in government do ac-

cept it. After all, a good many worked on the estimate. So it becomes imbedded in economic analysis. And since government outlays constitute about 15 per cent of the gross national product, the budget becomes heavily weighted with a fixed concept.

That is not the worst. Government tends to develop and parade a Pollyanna attitude. No President, Secretary of the Treasury, or Secretary of Commerce can make a public statement that business is not going to be good. Official statements—from those of President Hoover to Presidents Truman and Eisenhower—have ever been in an optimistic vein. The government has the responsibility of seeing that business is good. If it is not good, then it must try to help make it good. To proclaim poor business might create poor business. (The forecast of eight million unemployed in 1945-46 is the exception. Here the purpose was to impress on Congress the need for legislation. Also, it was a special situation—reconversion from the war.) Certainly, therefore, the public expressions of persons in government tend to be optimistic. And these opinions are the ones that are communicated to most persons. Doubts are communicated in private discussions, perhaps, but propriety calls for the "good word."

This is a political necessity. Every two years the government stands before the voters—in the Congressional elections. The party in power does not lose by glossing over unpleasantries. It keeps a stiff upper lip, regardless. That is the nature of the government: openly optimistic, regardless of what sober discussions go on in the inner councils. And that can have a self-mesmeric effect. Persons often think the way they talk!

Therefore we need a countervailing research power against institutional optimism: a nonpolitical organization whose sole objective would be to make a review of government economic statements and policies, not for the purpose of being critical and opposed, but for the purpose of being analytically objective. It could agree as well as disagree with government statements and legislation. Nor would it complain if government failed to follow its suggestions. It would look to the future, not beat dead horses.

No organization in existence today satisfactorily fills the bill. The Joint Committee on the Economic Report was set up by Congress for this purpose, but, unfortunately, the two-party system is not conducive to impartial research and reports. On critical issues, this committee usually splits.

Grover Ensley, staff director of the Joint Committee, did a remarkable job in developing a "joint report" on the President's 1954 *Economic Report* to Congress. But even then there were several exceptions and special points of emphasis by the Democratic members. And I doubt that even Ensley's exceptional diplomatic skill would be able

to get a truly joint report during a period of acute difference of opinion on ways and means of coping with either inflation or deflation. These reports tend to be compromises rather than objective analysis. If there were ever the prospect that the President's report were to be a major campaign issue in an election year, the chances of committee agreement would, in my opinion, be nil. Regardless of the objectivity of the committee's staff, the committee itself cannot be entirely objective. So it cannot perform this function.

Research organizations which sell their services often develop material which differs from government projections and policy. But such findings are limited to clients. The National Industrial Conference Board does some work in business analysis, but it has other functions and it depends upon subscriptions from business organizations. The National Bureau of Economic Research has the personnel for a task of this type, but it is devoted to long-term research rather than analysis applicable to immediate economic developments. It would not say "boo" on current events.

Labor research staffs frequently criticize the administration's program, but these criticisms are as much political as economic. Banks publish monthly reports on business, but are seldom single-mindedly devoted to business cycle analysis—with the purpose of informing the public about the strong and weak points in the business prospect, the efficacy of government policy, and the need for changes, if any. There is no lack of critics and analysts of government policies. But there is no organization set up for the specific purpose of making studies of cyclical progress and problems.

This organization would have to be headed by an outstanding economist—a person who could command the respect of economists of the New Deal-Fair Deal school and of the so-called "more conservative" school. (Professor Higgins classifies economists into four schools: the Latter Day-Laissez Faire, Keynesians, Marxists, and Institutionalists.) I am putting my stress here on political leanings rather than method or approach to economic analysis.

The organization would need a competent staff comprising specialists in government finance, banking, industry (broken down into hard goods and soft goods, with subdivisions for important sectors, such as automobile and steel), consumer savings and spending, building and construction, state and local government plans and outlays, etc.

A staff such as that of the Federal Reserve System would be ideal. The Federal Reserve, however, has to be looked upon as a branch of government. It cannot issue independent statements. Reserve research must be directed toward assisting the Board in making policy decisions which are co-ordinated with the policies of the Treasury. Thus complete research independence is neither possible nor, for that matter,

permissible. What is needed is a critic-commentator of government economic policy—a research group which would commend when policies seem wise, which would point out dangers if policies and statements seem unwise or impetuous.

Such a group is required because the government today commands more economists and statisticians than any other organization. Size equals power. The fact that recent results of the Council of Economic Advisers have been excellent does not guarantee the future.

Such an independent organization, with a strong board of directors, would command the attention of the President, his advisers, and the Congress. Its observations would alert persons in and out of government to shortcomings in government concepts, projections, and policies. It would remind all of us that the government's word is not absolute. It would guard against a stampede of monogenous opinion, fostered by government, which could lead to boom and then, perhaps, bust. Furthermore, it would furnish a yardstick against which to measure government forecasts. This organization, even as the Council, would put its judgment on the line in its reports and observations. Its survival would depend on its record—on the help it gives to all of us in understanding the economic currents and crosscurrents.

To summarize:

1. The government must undertake to improve existing statistics and develop any statistics necessary to increase understanding of the economic world we live and will live in. That is a virtual mandate under the Employment Act.

2. Statistics will not supplant judgment, however.

3. Long-term research is as much a government responsibility as short-term analyses of the business cycle.

4. To make up for the shortcomings of forecasting, we should invest the President with limited powers to undertake contracyclical action when Congress is not in session.

5. A counterpart of the President's Council of Economic Advisers should be established outside government to provide objective analysis of government plans and projections.

I think we are all humbly aware that the past is dead, the future is unborn, and the present is imperfectly understood. Sometimes I am sure we shall conquer the business cycle, that we shall limit declines to short periods of time and modest percentages. But I have doubts, too. At such times, I fear that not until after the next crisis will we know what kind of research we should have had to prevent it. But that does not mean we do not need research. We most decidedly do—better research and better judgment.

DISCUSSION

EWAN CLAGUE: At the outset let me emphasize that this is a good paper. Mr. Livingston asks the right questions, discusses the right issues, recognizes the handicaps and the necessities of forecasting, and makes some important suggestions.

My first comment is to indorse wholeheartedly Mr. Livingston's call for better statistics. Among those needs which were ranked highest by the economists was better construction statistics. This priority is correct in my opinion. Both from the seasonal and cyclical points of view, construction is probably our most important industry. At year-end in 1954 the economic situation would be quite different if the construction industry, instead of reaching new heights of activity, had turned downward. The recession of 1949 was counterbalanced in the same way.

Yet the statistics on construction are among the least satisfactory in our whole kit. The housing starts series of the Bureau of Labor Statistics has recently been revised and is now in excellent shape. However, it is a national series only. There are no corresponding data for localities, metropolitan areas, states, or regions.

There is no longer any data—national, state, or local—on the major characteristics of building, data which we formerly obtained. These would include the prices, the sizes, the materials used, etc. Correspondingly, we need information on the major characteristics of the buyers and renters, such as their previous residence, income, family size, etc.

Then, too, there was formerly a survey of builders which yielded information which should be of great value in forecasting the outlook for construction. This included the land holdings of builders, their building plans, recent sales experience, and their inventory of materials.

The data on dollar volume of construction put in place are fairly good, although they have some very important weak spots. Information on the construction of private nonresidential building, such as offices, factories, hotels, etc., needs revision and improvement; likewise the data on state and local public construction, which we are counting on to buoy up the economy during the next few years. We need and ought to have a good nationwide monthly series on the value of construction work started as well as on construction put in place.

Finally, there is urgent need of a good series on construction costs. There are some private series, but these are both limited and incomplete, and are based largely on the wages of building labor and the price of building materials. Over a long period of time these two will overstate building costs because there is no allowance for increases in productivity. What is needed in this field is nationwide coverage of various types of building structures and with some allowance for productivity increases.

Next, I should like to comment briefly on the problem of the establishment

of good government statistics. Government statisticians are competent practitioners and their integrity has been demonstrated time after time. There is no occasion for any criticism of government statistics on either of these bases. With respect to some other points, however, the situation is not so good. In general, there is not adequate maintenance and repair of statistical series. In order to avoid the obsolescence of which Mr. Livingston speaks, it is necessary to keep constantly checking the quality and significance of the data collected in any field. Furthermore, when the quality deteriorates there should be funds for repair and revision. This requires adequate funds specifically provided for this purpose.

Another weakness of government statistics is inadequate analysis and interpretation. This is not an exclusive function of government since there are many outside users, but in the first instance a minimum amount of analysis and interpretation is absolutely essential. Furthermore, this should be done by the collecting agency, since they are the only ones who are constantly in touch with the original data. Raw data are often misleading, as, for example, in unemployment compensation where the weekly claims figures often vary, not because of changes in unemployment, but because of administrative factors. The originating agency is the only one which can properly interpret these changes for the general public.

Finally, for a number of years public attention has been called to the gaps in government statistics. The Congressional Joint Committee on the Economic Report has called attention to this problem. Two things are needed: the elimination of series which are obsolete and the development of others which are urgently needed.

In conclusion on this point I should like to emphasize that in government statistics the public gets what it is willing to pay for in accuracy, frequency, and promptness of publication. Of course, there can be economy in statistical work—the development of sampling in recent years is clear evidence of that. However, there are limits beyond which it is not possible to go. It is the responsibility of the statisticians to make clear to the public the limitations on the data being published and the requirements for improvement.

I want to comment briefly on differences of opinion among economists. Mr. Livingston says that economists differ widely, but if we only had all the facts the answer would dictate itself. This is not quite true. There is one factor missing; namely, the value judgment of economists. For example, in an economic downturn some economists might favor a little inflation (or at least reflation) while other economists might recommend deflation (or at least letting things alone). Suppose that the eventual outcome would be exactly the same and a business recovery would take place. However, some people, including economists, will prefer the first solution while others will prefer the second.

These differences have nothing to do with economic analysis but only with personal preferences. Economists ought to watch this more carefully, since the public interprets all these differences as indicating the complete lack of any basic economic principles. My point in connection with Mr. Livingston's paper is that there is little use in gathering more facts and

"sweating out" more analyses if the differences of opinion are due solely to personal preferences and value judgments.

I want to say a few words about Mr. Livingston's remarks on forecasting by government officials. I do not take as dim a view as he does.

In the first place, all forecasting, if widely believed, tends to affect the results forecast, either directly or adversely. For example, if a high government official should forecast a sharp business depression (and publish it), he might possibly induce a recession through popular response to his forecast. (Perhaps this greatly exaggerates the influence which people generally would give to official judgments.)

Another example occurred this year. The outlook for home building took a little downturn in early 1954; so the government passed legislation facilitating the consumer purchase of homes. As a result, the downturn in the first half of 1954 was converted into a sharp upturn in the second half. So the forecasts of early 1954 had to be revised in the light of action to prevent their taking place.

Finally, I think that the reassurance by the President of the United States that the Administration would act forcefully to prevent a real business depression undoubtedly influenced the economic situation. Since the government has powers and resources capable of producing significant economic results, the business world can and does act on such reassurances.

I am not referring to Pollyanna statements which government officials may make concerning what business will do. I am referring to those statements which indicate what the government itself will do, on which government officials presumably have good judgment.

Finally, I should like to say just a few words about time and timing in economic policy. We economists have a most important obligation to make clear to the public the significance of time in economics. I stress this because the layman tends to expect results immediately. Even the economic actions which produce the quickest results take some little time to bring about those results. Some far-reaching policies may take months, or even some years, before their influence is fully effective. So we have not only the difficulty envisaged by Mr. Livingston; namely, that government policy-makers have to gauge the time allowances of their policies and therefore must strive to be forehanded in their actions. We have also the additional complication that the public does not always understand the time requirements and, therefore, will express impatience or dissent from policies which will work out all right, given a little more time. If I have any one suggestion to make, both to government economists and to those in business and other fields, it is that they try to keep the public informed on this crucial point.

Grover W. Ensley: I like the realism and insight of much of Livingston's presentation. I would underscore his statement that "in a society in which the government assumes responsibility for economic stability and high employment, forecasting becomes a part of the public domain." It is well to remember in our discussion, of course, that the federal government does not guarantee "stability and high employment," but rather to use its resources

and powers in co-operation with "industry, agriculture, labor and state and local governments" to that end. Under the circumstances, I would certainly agree that "national policy cannot be made without some assumptions about the future." Although we could quibble over the meaning of words like forecasting, projections, and assumptions, whether we forecast or not is academic today. The only question is, how can we improve our forecasts? This idea, of course, was clearly recognized in the Employment Act of 1946 and in that Act's prescription for the President's annual *Economic Report.*

The Joint Economic Committee has prepared and published a nation's economic budget annually for several years, not as a forecast or prediction, but rather as a projection for the next year of levels of economic activity needed to achieve the objectives of the Employment Act and to show the nature and magnitude of adjustments from present trends and plans and expectations needed in order to achieve the objectives. (H. Rept. 1256, 83rd Congress, 2nd session.)

No matter how good the process of forecasting or projecting may become, however, economists should not expect prompt compensatory legislation to result solely from a prediction by the Council of Economic Advisers, the Joint Economic Committee, or a private economic supreme court, that a turning point in economic activity will come at some given date during the coming year. Under many such circumstances we can only prepare in advance to legislate speedily at a time the turning point becomes evident, relying upon monetary policy, the built-in stabilizers, and administrative flexibility to cushion and to provide corrective forces against the initial effects of an unfortunate turn-around.

I would go along with Livingston in granting administrative discretion for increasing and decreasing public works expenditures within certain limits. I would suggest, however, that the Congress is often more sensitive to the needs for making tax adjustments than the Executive. And I am not as pessimistic about special sessions of Congress if need for economic legislation arises.

Livingston correctly says that the government must not stop with short-run analyses. It ought to undertake "studies into long-term economic trends or contingencies." Our Committee has given emphasis to this type of research. Several staff reports have focused on the long-run outlook. The most recent of these reports—released in November—was titled: "Potential Economic Growth of the United States During the Next Decade."

Naturally, I liked Livingston's reference to the recent hearings and report of the Subcommittee on Economic Statistics of the Joint Committee. All of the witnesses at these hearings placed the then pending census appropriation bill at the top of the "must" list. The subsequent appropriation to carry out the census of business and manufacturing resulted, in large part I believe, as a result of this testimony.

The Subcommittee report (H. Rept. 2628, 83rd Congress, 2nd session) also placed a high priority on four additional areas; namely, savings, inventories, consumer expectations, and business intentions. At the Subcommittee's request, the Board of Governors of the Federal Reserve System has created

five task groups of outstanding technicians to make exhaustive studies of present data, concepts, and sources and to propose practical programs for improving information in these areas. Information on the nature and scope of these studies was released by the Joint Economic Committee last week.

The President's program to be unfolded to the Congress in January, 1955, will propose significant steps forward in our statistical programs, based, in part, on the hearings and report of the Subcommittee on Economic Statistics. The profession and other private users will all need to get behind this program and see that it is legislated.

I have only one real disagreement with Livingston's paper. It deals with the recommendation that there be created a "private counterpart" to the government's Employment Act agencies. He puts it in terms of "a countervailing research power against institutional optimism." At the outset, let me make clear that we are for private economic research to supplement and assist the Council of Economic Advisers and the Joint Economic Committee in carrying out their statutory responsibilities. The Employment Act recognizes the important role of private research. We know of the good work of the National Planning Association, the Committee for Economic Development, the Twentieth Century Fund, and the many, many other private agencies.

But I would be very skeptical of recognizing one of these agencies as being the institution to which we must turn as sort of a supreme court of economics, even though their views were not binding. I am a little uncertain as to who is supposed to appoint or designate this private economic council of supermen with their priestly powers to issue oracles. I raise this point because it seems to me that the entire proposal for such a private institution as official critic of government economic analysis and policy is in conflict with American principles of responsible government. We have always conceived of agencies performing functions upon which governmental policy is to be founded as necessarily being responsible to the people. Suppose for the moment that we had had such a private council a year ago. Suppose, also, that it would have been headed by as disinterested and objective an economist as Professor Colin Clark. Now if Clark's dire and ill-founded predictions and corrective program of a year ago had been followed, the resulting embarrassment would have plagued the party in power for years; yet our friend Clark would have escaped almost unscathed back to the cloisters of Oxford University and temporary oblivion. An irresponsible economist can live in oblivion, but a responsible political party cannot.

Livingston is concerned about the objectivity of government economic research. He correctly does not question the professional competence and responsibility exhibited by the rank and file of government economists. On this we certainly agree. I know of no more able, sincere, nonpartisan, objective —and I might add underpaid—group of technicians than in the federal career service. I am sure the economic profession regrets the wringer through which the career staff of the old Council of Economic Advisers went in the spring of 1953. Thanks to the professional standing of the three members of the present Council, restoration of a professional staff was possible. A bad precedent, however, has been established in that executive agency.

Perhaps the party line must be followed in the Executive Branch, once a decision or recommendation has been formulated, but the Executive is just one branch of the federal government. There is the Congress where the final policy-making power rests, and no one can charge that the Congress always follows a party line. Furthermore, minority reports are useful in explaining opposing views to the public.

I do not believe the facts bear out Livingston's statement that all government operates in an optimistic vein. That has not been true of all Council reports, nor has it been true of the Joint Economic Committee reports and staff materials. Livingston himself refers to the pessimism of the Administration in 1945 and early 1946. The Administration was seriously concerned about inflation in 1948. I believe the Joint Committee's hearings and report of February, 1954, dampened somewhat the optimism expressed in the President's *Economic Report,* and put into better perspective the need for tax revision—including one billion dollars of excise tax reductions in the face of Administration opposition, more liberal highway and rural electrification authorizations, farm supports, liberal housing, and social security programs.

It is important, of course, for government to provide courageous leadership. In so doing it may give a confident air with respect to the economic outlook, but this can certainly boomerang with resulting loss of public confidence if based on unfounded or false optimism—and successful public officials realize that fact.

For the very reason that elections come every two years, our elected representatives are alert to reality. As a matter of fact, I doubt if any group is more alert to reality than elected public officials. Livingston said: "The party in power does not lose by glossing over unpleasantries." But it does not win by glossing over unpleasantries, either, and the unemployed congressmen walking the streets every other November prove it!

The Joint Economic Committee is criticized by Livingston for "usually" splitting along party lines. But this was not true of the rather historic report of the Douglas subcommittee in the spring of 1950, when it recommended that a flexible monetary policy replace the rigid one. It was not true of the Joint Committee in July, 1950, when it unanimously recommended an immediate and substantial increase in taxes to offset the inevitable inflationary pressures brought on by the Korean war. It has not been true on countless other issues dealt with in Committee reports over the years.

It is to be expected that the underlying and differing economic philosophies of the two major parties should come out in Committee reports. But if there is an emergency with clear-cut evidence of marked inflation or marked deflation—and we have seen such emergencies—I am confident the Joint Committee and the Congress would reach a remarkably wide area of agreement on major economic policy in a sincere endeavor to deal with the problem. I am thinking about July, 1950. Also, had the recession not stopped last summer, we would have seen united action on antirecession measures. The most troublesome problem is formulating policy in a period of uncertainty with a mixture of trends and forces at work—when honest differences of opinion may be expected. Unfortunately, we have not developed anything comparable to the

"rabbit" test which will enable us accurately to predict economic turning points.

I dare say there is more difference of opinion on the economic outlook and economic policy among so-called "objective" economists than among congressmen. Until recently I would have hedged some in making such a sweeping statement because of the tariff issue. But I am not so sure now, having read articles and briefs written by a Harvard professor on the textile industry, a Dartmouth dean on the chemical business, and other economists on other industries and regional problems. Livingston gives economists a batting average of .500 on short-range forecasting. The fact of the matter is that honest men, objective men, differ as to what the economic outlook is and what appropriate policy should be. This is very desirable in an area in which there will always be uncertainty as to the facts and their implications. Disagreement and debate serve to bring out all the possibilities.

We have private research and economic interest groups and universities bubbling over with professional economists analyzing the economic outlook, criticizing, and recommending policy. We have the fourth estate, so ably represented at this session today. We have a form of government which encourages and guarantees this process. We are not short on outside and independent analysis and criticism and recommendations, and that is good. Our Committee doors are always open to economists who wish to give us the benefit of their thinking. The Joint Economic Committee's hearings provide an opportunity for all segments of the economy to present their views to the Congress. But it is the essence of our system of government that our democratically elected representatives synthesize these analyses and arrive at workable programs. That is their responsibility, and we can hold them accountable.

STANLEY LEBERGOTT: Josh Billings once remarked: "Everyboddy wants tew talk, few want tew think, and noboddy wants tew listen." We must, however, surely make an exception for this fascinating and thoughtful discussion by Mr. Livingston. I am going to address my comments to the questions which he asked in his survey and to the answers he listed.

What data are needed to develop policies for economic stability? The answers to his questions on this subject provide an interesting paradox. In Mr. Livingston's apt phrase, the respondents found that the federal government needed "forty different types of statistics." But when they came to their own needs, they found no gaps whatever: "There were no positive expressions of what additional information would have led to firmer convictions about policies to be pursued." Surely they must have overstated the government's needs or understated their own.

Let us, nevertheless, concede that we do have significant gaps in our statistical armory. I believe that the forty suggestions reveal an unfortunate hope—a hope that statistics can be so perfectly tailor-made that economic analysis would be pretty much unnecessary. Let us examine some of the needs that were mentioned. One is the lack of quarterly deflated GNP data. This is a gap indeed. But is it serious? Anyone who examines the basic data will, I

think, conclude that a cost-of-living index will do remarkably well for quarterly deflation of the GNP data between the available annual estimates. Another gap listed was "the number of unemployed persons not receiving employment benefits." But we can approximate trends in this group tolerably well by deducting the number who receive benefits (BES) from the number employed (Census). More data on industrial accidents were also demanded. Considering that Mr. Livingston's question concerned those data needs "which prevent or hinder the federal government in making effective policy decisions to maintain economic stability," one can only conclude that this suggestion was made in jest.

More detailed data on new orders, sales, and inventories? Indeed such data would be an advance. Yet considering the quality of our existing figures, it is somewhat surprising that the need expressed is for more rather than for better data. That needs for data do exist there can be little question. This survey points out some. But we would do well not to take what may be offhand opinions of twenty-six respondents as a very positive basis for judgment. We shall, in addition, want to review such considered statements as those of the Watkins Committee (to which Mr. Livingston made an invaluable contribution) and the admirably succinct summary of the data needed for making policy decisions on economic stability in the statement by the chairman of the Council of Economic Advisers to the Talle Committee.

Should government study the impact of its economic policies and study long-term trends? Asking such a question comes close to asking whether parents should get up early on Christmas morning to look at the children's presents: there is little alternative. The Treasury must study the state of the bond market before launching a new issue. The Reserve Board must evaluate general economic conditions at length to anticipate the impact of a change in reserve or margin requirements. The Secretary of Agriculture has to review the impact of a proposed set of parity prices for the forthcoming year, etc. However, it is clear that many of these studies will not be publicly available, as is, I think, implied in the question.

Moreover, while long-run analyses are made, they are undoubtedly not made as systematically and as coherently related to each other as is implied in Mr. Livingston's question. The Census Bureau, for example, has made long-term projections of both population and labor force. The Office of Business Economics has projected markets for a broad range of industries. Transportation activity has been anticipated by the ICC and by Public Roads. Forecasts of exports and imports have been made for use by international agencies, etc. In sum, a considerable amount of such work has been done. If I may interpret Mr. Livingston's question to that effect, a considerable amount should continue to be done, but perhaps more systematically, with greater integration and with more presentation of the results for broad public use wherever possible.

To Mr. Livingston's proposal for "a private agency, to be the private counterpart of the President's Council of Economic Advisers" I would say: "Come on in. The water is freezing, the bottom is rocky, and you'd better watch out for the old tomato cans." The more economists who address them-

selves to these problems the better. I am certain, for example, that reviews and judgments on the state of the economy made by Messrs. Burns, Jacoby, and Stewart would be of great value for government policy making even if they were outside government service, heading such a private agency.

I would add two limited comments. First, that if there is "a government economic line," as Mr. Livingston suggests, there is nothing like the uniformity of public utterance nor the restriction of data that this would imply. Read the *Survey of Current Business*. Read the *Federal Reserve Bulletin*. Read the reports of the Agricultural Outlook Conference. You will find them, perhaps, stuffy, reserved, in broad agreement. But they do differ. More importantly, they give the facts. They provide the basis for independent judgment by economists throughout the country. Moreover, there is considerable point in not seeking *a* single authoritative critic. In a pluralistic economy such as ours, is not there point to combining and balancing off the statements of both political parties (in the invaluable reports of the Joint Committee on the Economic Report), of the National Planning Association, the CED, the AF of L and CIO, the Chamber of Commerce and NAM, etc.? Each can give us an important perspective on the problem. Each has a significant contribution toward a combined judgment. (I would venture an incidental comment—which, however, does not detract from the merits of this useful proposal. Just as desirable as it would be to have another competent group of economists working in this area, so one could anticipate a gradual attrition of prestige if they were to engage in it: the prestige of economists is usually inversely proportional to the number of detailed predictions they make.)

On Mr. Livingston's final point—the desirability of an antideflation policy—I will not comment directly. The problems of an automatic policy have been well canvassed and this enticing subject is outside my bailiwick.

Although, as Mr. Livingston points out, such a policy would reduce the need for CEA projections, we will, of course, continue to need projections and forecasts. The Treasury, for example, will still have to forecast something like GNP, personal income, and corporate profits totals to make its forecast of government revenues.

In evaluating the need for such a policy, we would do well to consider what I would call the visible hand theory. I would not challenge Mr. Livingston's assumption that even with an automatic policy Congress would not grant powers which the President could exercise before five million persons were unemployed. Yet major steps were taken in 1954, without such a policy, when unemployment was under four million. I refer to the action of the Congress on excise and personal taxes early in 1954 and the program of the President adopted by the Congress in the Housing Act of 1954. In practice, Congress may be willing to support more substantial intervention in economic affairs than it would accept as set down in general premonitory legislation.

BERT SEIDMAN: The American Economic Association is to be commended for including the problem we are discussing in this year's program. It is a subject which should encourage us as economists to take our minds off detailed

problems in specialized fields and to step back for a moment and appraise our work as objectively as we can.

Mr. Livingston has set the stage for such a self-analysis by economists. His paper stimulates us to consider and appraise the role we economists can and do play in the formulation, principally by noneconomists, of public policy.

At the outset, I want to heartily endorse Mr. Livingston's emphasis on the urgent need to fill the gaps in statistical data. A number of investigations during the past year have concentrated on this problem. There is an increasing awareness, principally, but—I am happy to say—not exclusively, on the part of economists and statisticians, of the need for a wider range of and more accurate statistical information.

I particularly like the stress placed by Mr. Livingston on the disturbing fact that we do not now know which sector of the economy will be strategically most critical in a future period of economic stress and therefore we cannot be sure as to what types of economic data will be most needed. If anything, this should reinforce us in the determination to fill as many statistical gaps as possible.

If I had to put all my eggs in one basket, I would especially emphasize the need for more and better productivity data. It has become trite to forecast the tremendous technological improvements and concomitant rapid increases in productivity we will witness in the years ahead; but this is a case where repetition of a prediction does not detract from the importance of its implications. Since measurement of productivity changes is essential for determining labor and capital requirements as well as the production potential of the economy, it is most important that we concentrate now on improving and expanding productivity data.

If I had time I would like to elaborate on the types of statistics we most urgently need, but this is not our principal concern. Perhaps it is enough for me to agree wholeheartedly with Mr. Livingston that there are serious gaps in statistical and economic data which need to be filled in as rapidly as possible.

Now, what about this business of forecasting? Many economists feel that economic prognostication is greatly overemphasized, and that this is especially unfortunate in view of the tendency for the general public to regard the projections of economists as precise predictions. But regardless of the desires of professional economists, economic forecasting is here to stay. Moreover, we should not deceive ourselves into believing that economic forecasts are being made only by trained economists—whether in unions, banks, corporations, universities, or government. Actually, economic forecasts are also being made—often with no conscious realization of it—by literally millions of people who are not technical economists and know little or nothing about economic data.

Let me give an example from the field of collective bargaining. We union researchers are trying to provide as much data as possible for our trade-union constituents for collective bargaining purposes. We are gratified by the increasing use to which our economic data are put. But we are also aware that many unions, as well as many employers, particularly on the local level and in small plants, rely not on formal economic data but on their own feelings, intuitions,

or what have you, as to economic prospects when they sit down at the bargaining table.

Actually, many economic decisions of great importance—certainly of great importance in the aggregate—are made on the basis of just such lay judgments of the future of the economy by congressmen, consumers, farmers, businessmen, union representatives, and many others. Their decisions greatly affect the course of economic trends. Indeed, they may determine whether the projections made by professional economists are borne out by actual events. What should particularly give us pause is that, as Mr. Livingston has pointed out, since economists have had at best only a fifty-fifty record in this business of forecasting, our record may be no better than that of the millions of nonprofessional forecasters.

This may seem to be a defeatist and pessimistic note, but that is not my intention. Rather it seems to me that these facts present a challenge to economists. Since I have no great faith that the judgment or intuition even of economists can be appreciably improved, I would stress again the need for sharpening the tools of economic analysis available to economists. This does not mean that we should seek data for their own sake, but we should make every effort to obtain every bit of data we can get to aid our admittedly imperfect judgments. This means most urgently a halt to the attrition of the government statistical programs which, after all, provide us with the main body of statistical information we must have for effective research and analysis.

I react with mixed feelings to Mr. Livingston's suggestion that the government has a responsibility to engage in long-term economic research. Some long-term research by government agencies is certainly desirable both as a means of making more useful and meaningful the short-term data collection, research, and analyses of these agencies and also to contribute to a more general understanding of fundamental economic problems.

On the other hand, it seems to me that precisely because the government agencies cannot, by the very nature of their status, achieve complete, or even nearly complete, objectivity, I question whether we should place our main reliance on government for studies of long-term economic problems and developments. I would hope that our major source of light on such questions would continue to come from the universities, the National Bureau of Economic Research, and other independent groups.

Mr. Livingston's fourth point—his recommendation that the President be given limited powers to undertake emergency antideflation action—was not included in the preliminary draft of his paper; but if it is an afterthought, it is an extremely worth while and constructive one. While I am not prepared to comment in detail on his suggestion, I do think its implementation would strengthen our economic armory. The President's hands are not completely tied, and there is some grounds for feeling that his existing authority has not been used fully or quickly enough. Nevertheless, his authority to combat incipient depression needs to be strengthened. I do think that the five million unemployment figure Mr. Livingston suggests is too high and that antidepression action ought to be taken before economic activity declines to that level. This is perhaps a detail—although an important one. But I heartily

agree with the general principle embodied in Mr. Livingston's recommendation.

This brings me to Mr. Livingston's intriguing suggestion for the creation of a private counterpart to the Council of Economic Advisers. My first impulse was to endorse this suggestion enthusiastically.

What Mr. Livingston has said about the lack of impartiality of the various private and governmental agencies engaged in economic research and analysis is certainly true. The biases of such groups are for the most part not conscious and are certainly not deceitful, but they do exist and they cloud the impartiality of their work.

I would certainly agree with Mr. Livingston that the President's Council of Economic Advisers labors under such a handicap. Dr. Burns might have thought when he became chairman of the Council that he could somehow maintain an Olympian impartiality and no doubt he has sincerely attempted to do so. But by now he has found that the Council—like any other agency of the government—is of necessity merely an arm of the Executive. This is no less true of Dr. Burns's Council than it was of Mr. Keyserling's, however more willingly Mr. Keyserling may have accepted that role. Moreover, we have seen that when Dr. Burns was unwilling to subordinate himself to the over-all policy of the Executive, as in the case of the so-called "Midyear Economic Report" issued by the White House last summer, he was simply brushed aside.

Is the answer to the admitted biases of the many existing agencies carrying on economic research and analysis and making economic projections a private council of economic advisers? As attractive as Mr. Livingston's idea is, I think that consideration of his proposal must lead to its rejection.

First of all, how do you get a body which would have the universal acceptance which Mr. Livingston rightly feels it would need? Is it really possible to find to head this organization "an outstanding economist—a person who could command the respect of economists of the New Deal-Fair Deal school and of the so-called 'more conservative' school"? I have very grave doubts that such a person actually exists or that he would long retain such an exalted status if required to assume the task Mr. Livingston would assign to him. Nor would the job of assembling a staff of experts in various fields with the same measure of universal acceptance be an easy one.

Let us suppose that somehow these hurdles can be met. Do we really want to have any economist or group of economists—regardless of how expert, respected, or accepted—placed in a position as the final arbiter in questions of economic analysis and forecasts? I, for one, prefer the existing situation where consumers may pick and choose among economists and their wares and select the product which will best meet their needs for economic information.

I have the very strong feeling that if we were to accept Mr. Livingston's proposal for a private council of economic advisers, we would simply be jumping from the frying pan into the fire. Mr. Livingston urges his suggestion on the grounds that "it would remind all of us that the government's word is not absolute." He tells us that the new organization "would guard against a stampede of monogenous opinion, fostered by government, which could lead to boom and then, perhaps, to bust."

It all sounds very fine. But what about the danger that the new organization

would have the very weaknesses that Mr. Livingston warns us against? Here would be a new fount of monogenous opinion on which government officials and other policy-makers would have every reason to rely because of its supposed absolute objectivity and exalted professional caliber.

Yet we all recognize that not even the best of economists is infallible. In fact, I doubt if even Mr. Livingston's private council of economic advisers would better by much the .500 batting average of the general run of economists. We must not run the danger of establishing an organization which will be virtually immune to criticism when we know full well that it will not always be right. Rather than attempt to create a final arbiter in the field of economic ideas, I would urge that we direct our energies instead to improving the tools of economic research and analysis for the use of all economists.

MERRILL A. WATSON: The instructions for the panelists in this session, although clear, offered great latitude. We were told that the session was designed to present an appraisal of the adequacy of government statistics, particularly for the public and private purpose of business cycle analysis and economic stabilization. We were told further that we might discuss whatever we found challenging in the main speaker's paper and make whatever comments we wished. My discussion of the speaker's paper will be from the viewpoint of the business economist.

The speaker has drawn five conclusions in his paper. The first, based on replies from twenty-five economists, is that the government must undertake to develop a better-equipped statistical armory. The second deals with the changing importance of economic data, the shortcomings of forecasting, and, above all, the need for judgment in the analyzing of data. In his third point the speaker emphasizes the need for long-term economic research by the government. Fourth, he stresses the need for greater flexibility and automation in our built-in shock absorbers and greater authority for the President. Fifth, a new private agency, a counterpart of the Council of Economic Advisers, is recommended.

I should like to comment first on some of the questions contained in the survey of economists. Certainly a few of the answers indicate a reaching for somewhat irrelevant data, although there is no use in debating that point here. One might, however, wish the respondent who stated that "we don't need more data; we need better judgment" had expanded on his views.

I am rather surprised that only a few of the economists surveyed emphasized the need for more current information on orders and inventories, particularly in private industry. There are important statistical gaps in this field. My own observation has been that there is a great need for more and prompt information of this type for forecasting purposes in individual industries. For example, in such private statistical-gathering organizations as trade associations there are very few groups which collect the necessary data for measurement, analysis, and forecasting of the short-term cyclical movements which we often term buying movements or inventory accumulations. A complete picture here, for example, would show the flow of raw materials, production of finished goods, sales, and inventories in dealers' hands for a manufacturing

group selling to the retail trade. It would be too much to hope for a measure of inventories in the hands of ultimate consumers. This information might be supplied by a weekly index of purchases of raw materials; a weekly index of new orders received for finished goods; and monthly data on production, sales, and inventories at the manufacturing level. When to this is attached a picture of sales and inventories of finished goods at the retail level, collected on a monthly basis, a fairly comprehensive "flow chart" for an industry is available.

Some experimentation in this field has indicated that such a flow chart will reveal not only the extent of inventory accumulations and shortages but also the turning points in short-term industry cycles. I might also say that to some of us in industry the collection of this type of information is a general goal. In far too many cases in manufacturing groups we have been placing emphasis on the collection of monthly information on production and inventories. This has provided a basis for historical measurement of long-term trends but has been of little value in detecting and measuring the short-term industry movements which plague many of the consumer goods industries.

I should not like to leave the impression that I believe that the filling of these statistical gaps and the developing of a flow chart of this nature will play an immediate part in curtailing or eliminating these short-term industry cycles. Frankly, I do not know whether it will or not. My observation so far is that the flow charts are extremely interesting and may, over the longer term, be used to a greater extent by businessmen in determining policy. So far, they appear to play a minor role in influencing business policy one way or the other. In the first place, businessmen have not yet developed enough confidence in the information to make proper use of it. Second, businessmen who are participating in an inventory-building boom by shifting their own inventories to their customers' shelves even with proper warning are not inclined to stop and permit their competitors to enjoy increased volume. Once an industry is engaged in this pleasant activity, it is likely to continue until retail shelves are filled, at which time the entire "buying movement" subsides. However, I believe that such a flow chart of activity over the long run will be used more intelligently by business.

The third question was divided into two parts: "What economic policies followed by the government in the past do you consider most open to criticism?" And, "Would better statistical data or research have pointed out beforehand the shortcomings of these policies?" The latter part of this question was apparently not answered. With respect to the first part, the economists were about equally divided, according to their liberal or conservative leanings. What can be said here except that the division of opinion is what might be expected of a sample group of economists and that an advisory board composed of such a group would not be particularly helpful to a policy-making administrator.

The fourth question ("What economic policies would you recommend at this time?") is really a continuation of the third and produces the same division of opinion, illustrating again the dilemma of a public administrator depending upon the economist for proper theoretical guidance. This concludes my comments on the survey of economists.

In his second conclusion the speaker points out some forecasting errors and stresses that additional statistics will not reduce the need for judgment. He supports the view that probable errors are still too great to place complete confidence in forecasting as a basis for developing adequate countercyclical measures to promote economic stability. Certainly this can be said without in any way denying the fact that substantial gains have been made in the way of improved forecasting in the last few decades. New data have been developed and new approaches to the use of data have contributed to progress in forecasting. Furthermore, the many studies of business fluctuations have provided a basis of knowledge without which stabilization policies dealing with inflation, deflation, and unemployment could hardly have been attempted. I am sure we can agree that this progress is likely to continue in the future and that the interest in forecasting will continue as great or even greater than it is today. The more forecasting we do the better we shall do it.

As another point, the speaker makes it clear that while we cannot have complete confidence in economic forecasting to provide an accurate map of economic developments, neither can we depend on automatic snubbers or built-in stabilizers to provide sufficient counteraction when economic events require it. He therefore suggests the President be provided with limited powers to undertake contracyclical action when Congress is not in session. In theory, it is hard to argue this point. However, there are some real hurdles to surmount in reaching this goal.

In the first place, it involves, as the speaker recognizes, the problem of a delegation of powers by Congress. This Congress has not always been willing to do, and it may well involve a substantial political struggle without result. Assuming that the powers would be granted, however, there is then the question of co-ordination of the rather complex governmental administrative structure to get prompt action. Finally, there is the problem of when and what kind of action should be taken. The conflicting advice of economic advisers with respect to action that should have been taken during our recent inventory recession has already been mentioned. If, as a result of this conflict of economic opinion, administrators would have had to form their own opinions on these economic matters whether or not they were equipped to do so, the action taken may or may not be good for the economy.

Finally, practically all of these issues have political overtones. Even with a stand-by committee composed of representatives of both parties the acceptability of any proposed administrative action will invoke great argument. Unless the economic situation is deteriorating to such a degree that all political elements agree on the need for immediate action, there may well be political reverberations which will cause hesitancy and, in fact, postpone action.

As his fifth and last point, the speaker proposes that a counterpart of the President's Council of Economic Advisers should be established by some foundation to provide objective analysis of government plans and projections. Such a group, he believes, would be free from the restrictions which frequently bind those in governmental service.

It may be regretted that the speaker did not include this proposal in his questionnaire to economists so that we might have observed some additional

reactions to this proposal. Perhaps the opinions would have divided about equally in answer to the question on the need for more economic data where a little better than half wanted more data and slightly less than half disagreed or did not care to answer the question. Probably most of us have an insatiable demand for more data and more information and would not, therefore, disagree with any proposal which might provide additional economic information on instability in our economy.

However, I am sure that even an outstanding group of economists working from Olympian heights would have the same problems as economists generally. In the first place, as we have seen, different economists may use the same data and yet arrive at different conclusions. Second, even if unity of approach and conclusion is achieved, the recommendations of the group would probably be characterized as representing either the conservative or liberal school of economic thought and be completely unacceptable to economists of the other school. If its conclusions should be found to be in direct opposition to those of the Council of Economic Advisers, the resulting debates and arguments would add confusion rather than build public confidence in economic research.

Finally, one might wish that an additional recommendation or proposal had been made for developing a broader understanding of the need and importance of economic research both in the political and business field. There is one recent particularly glaring example of how public policy-makers ignore the need for economic data. It was only a short time ago that a Congressional committee decided that such basic economic yardsticks as the various censuses were unnecessary, at least for several more years. And that, in spite of the fact that Congress had undertaken certain responsibilities with respect to economic stability and with the knowledge that there have been great changes in the economy since the last census. To most of us the postponing of the census of manufactures, for example, would have been a catastrophe. Yet it was only through organized effort and the support of many groups that these measures of our economic growth were reinstated.

Moreover, I am sure that the congressmen who voted against the appropriations of funds for this purpose have not changed their minds as to need for the information. This experience can be more or less duplicated by many business economists who are waging a constant fight for a better understanding and appreciation of economic data by businessmen.

It is not surprising, therefore, that all too frequently congressmen and public administrators are not guided by economists, even where good economic research has been done and carefully thought out recommendations are available. Whether it is in the field of business, agricultural policy, labor, or taxes, the ultimate decisions are made by legislative or administrative bodies more responsive to public will and opinion than to sound economic policy.

It is for these reasons, I think, that many business economists experience more frustration in marketing their own product than in finding adequate data. One of the real problems here is the matter of communication. Economists have little difficulty in communicating with each other. But many of us have great difficulty in communicating with the average businessman and with politicians. Part of the difficulty stems from the use of the type of lan-

guage so well described by George Orwell in his admirable essay, "Politics and the English Language." Part comes from the fact that many politicians and businessmen who constitute the market for economic data are even now skeptical of the value of economic research and have little confidence in what economists and statisticians tell them—particularly when different economists tell them different things. Certainly progress has been made in winning the support of businessmen and politicians, but it has been agonizingly slow.

In summary, it may be said that economic research has made it possible to develop a foundation for public policies which can combat the instability in our economy. The economist and economic research are gaining increasing recognition and playing a growing part in providing an analysis of the reasons for instability and prescribing methods of treatment. The influence of economic research for both public and private policy determination is spreading, although at a slow pace. There are important statistical gaps existing today and they should be filled. But what can be done to speed up and broaden the use of the economic data we already have? The prescription here is not easy. Certainly improved communication between the economist and his market will help. In addition, however, if some program either through public or private channels could be organized to broaden the public understanding of the need for and use of economic data and their importance in solving the problem of business instability, it would be most helpful.

ECONOMIC STABILIZATION, FORECASTING, AND THE POLITICAL PROCESS

PROBLEMS OF FORECASTING FOR ECONOMIC STABILIZATION

By ROBERT C. TURNER
Indiana University

I

When the Congress, in the Employment Act of 1946, required the President, in his *Economic Report* to set forth "current and foreseeable trends" in the levels of employment, production, and purchasing power, and the Council of Economic Advisers "to gather timely and authoritative information concerning economic developments and economic trends, both current and prospective . . .," it was evidently their judgment that forecasting could, and should, be employed as a tool of economic stabilization. Yet, there is a fairly common disposition in economic circles to reject forecasting as impossible or too unreliable to be useful in economic stabilization. Indeed, one of the authors of a recent, authoritative symposium on income stabilization reached the conclusion that "in its present stage of development economic forecasting is much too inaccurate to be used as the basis for changes in stabilization measures."[1]

There are good reasons, of which you are all aware, for this pessimistic view of the potentialities of forecasting. But the plain and stubborn fact remains that—I should warn you that this is a main thesis of my paper—there is no escaping the necessity of economic forecasting. Present actions have their effects in the future. If government has any stabilization purpose at all, then in making present decisions as to these actions it inevitably must make frequent, recurrent, and often crucial forecasts. They may be made consciously or unconsciously, scientifically or unscientifically, at one end of Pennsylvania Avenue or the other, but they are still forecasts. There are just two issues, which we hope are not wholly unrelated: (1) how good is the forecasting going to be and (2) how much are economists going to participate in the process?

Before we get down to serious business, let me dispose of two refuges to which economists sometimes flee, especially those who, by virtue of official position, are actually called upon to make forecasts. One is to eschew forecasting as being beyond the competence of any economist,

[1] "The Role of Economic Forecasting in Income Stabilization," by Everett E. Hagen, in Max F. Millikan (ed.), *Income Stabilization for a Developing Democracy*, p. 200.

and when a policy decision or recommendation must nevertheless be made, to assume "no change" in the level of general business activity. This is obviously an implicit forecast, and simply forces the user of the forecast to decide whether or not the assumed "no change" is correct, and if not, to make the necessary adjustments. The other is to make a forecast but to becloud it with a fog of qualifications and ambiguous adjectives of sufficient density to render it largely invulnerable to later attack, but also largely opaque from the viewpoint of those required to make policy decisions. This is another case of passing the buck.

I said a moment ago that forecasting is necessary if government has any stabilization purpose at all. I am assuming throughout this paper that government does have a stabilization purpose and that in fact we want to do an effective job of economic stabilization. The ultimate objective would presumably have two facets: first, the achievement of a long-run growth in national output which does not depart significantly from our capacities for growth, within the limits of voluntary preference for leisure over goods and services, i.e., maximum technological advance coupled with a minimum of involuntary unemployment; and, second, a stable price level, with a gentle upward trend viewed as a not altogether undesirable consequence but not adopted as conscious public policy. Conflict and compromise with other national policy objectives will inevitably preclude full achievement of this goal, but within the limits thus determined, our success in economic stabilization will be measured in important part by the extent to which we are able to make reliable and useful forecasts and to act intelligently on those forecasts.

II

The conventional broad classification of stabilization measures is automatic versus nonautomatic. Automatic stabilization measures presumably require no current forecasting; the forecasting was implicitly done when the law was enacted. The problem relates to their effectiveness. Our system of automatic stabilizers is not symmetrical; not all of the stimulative automatic actions in deflation are matched by corresponding repressive automatic actions in inflation. Moreover, as has often been pointed out, the automatic stabilizers can, at best, mitigate the severity of a decline, and beyond a certain point (e.g., protracted unemployment), their stabilizing effect dwindles toward zero. It is conceivable that a system of automatic stabilizers could be invented which would absolutely stabilize real income, but it would require a rather wide departure from capitalism as we know it. I do not mean

to understate the significance of existing automatic stabilizers. It may well be that they offer a sufficient solution to minor and very short-run fluctuations. But, in the contemporary economic environment, if fluctuations of more than a minor character are still possible—as I believe they are—the automatic stabilizers offer only a partial and limited answer to the problem of economic stabilization.

The nonautomatic stabilizers, however, require conscious decision and positive action. It takes time to recognize and identify an economic development requiring action directed toward stabilization, to determine the appropriate action, and to translate the policy determination into law or regulation—especially if a Congressional enactment is required. A still further time interval ensues between the change in law or regulation and its effect upon incomes, spending, and other economic factors. Such stabilization actions will affect economic behavior usually several months, and often as long as a year or more, after the need for action is recognized. To stabilize effectively, a decision to counteract a decline must be made well in advance of the decline. But this can be done only with forecasting.

It is no solution to the forecasting dilemma to stipulate that stabilization action should be determined by rule of thumb after the fact; e.g., that counterdeflationary measures should be taken after unemployment has risen to a specified percentage of the labor force or that counterinflationary measures should be taken after the BLS index of consumer prices has risen by x per cent for y consecutive months. A forecast is inherently implicit in such a rule of thumb; namely, that recent directions of economic change will continue or at least not be reversed. The tightening of Federal Reserve credit controls early in 1953 is a good example of a delayed action after the fact where the implicit forecast turned out to be considerably in error. The easing of credit policies a few months later, however, is an example of an action which would scarcely have been indicated by an after-the-fact rule and which, therefore, was presumably based on an explicit forecast—a forecast which turned out to be pretty good.

Let me hasten to add that taking action after the fact is usually better than nothing. It will produce an answer which, though probably inadequate and inevitably tardy, is in the right direction more often than not, simply because the momentum of our economy is such that straight, short-run projections of recent tendencies turn out to be right more often than not. Nevertheless, to the extent that anything more than a compensation for past fluctuations is attempted by taking action after the fact, implicit forecasting is involved; it might be called "forecasting by assumed momentum."

III

So far I have argued that forecasting is necessary to successful stabilization without indicating what kind of forecasting I have in mind. Forecasting by a government agency for stabilization policy purposes differs in one important respect from general economic forecasting for private business purposes. In either case, the forecast must be based upon certain initial assumptions as to forces outside the economic system per se, such as war, cold war, or changes in law, or other governmental action. The private forecaster may simply assume no change in government policy on the ground that political forecasting is beyond the competence of the economist, and then leave it to the user of his forecast to make his own assumptions as to changes in government policy and make his own adjustments in the forecast. Or he may make a best guess as to what the political process is likely to bring forth in the way of tax changes, expenditure programs, and the like, and then having stated his assumptions, proceed with a definite forecast. There is nothing inherent in the method to preclude a forecast of another 1929-32.

In the case of a forecast by a stabilization agency, however, government policy is not a completely exogenous variable. The forecasting activity is itself a part of the process of policy determination. A forecast by the Council of Economic Advisers, for example, will normally involve two steps. The first is a preliminary forecast, based on the assumption of no change in private or public policies (or perhaps on the assumption of certain changes which are expected to be made for nonstabilization reasons). This preliminary forecast might well indicate that recessionary tendencies are in prospect. But it cannot stop there. The whole purpose of the forecasting process is to identify those policy changes which are needed to prevent a depression from developing—changes which are needed to make the preliminary forecast become untrue. It must proceed, after identifying these needed changes, to incorporate them into its analysis, to forecast the effects of these changes, and thus to point the way to satisfactory levels of economic activity. Such a forecast is not likely to be a flat prediction of a depression, certainly not another 1929-32. A better term, perhaps, for this kind of a forecast is a "conditional economic projection"—a projection that certain levels of economic activity should prevail on condition that prescribed changes in public policy, and perhaps also certain changes in private policy, are made.

This does not necessarily mean that such a projection by the Council of Economic Advisers must always point to a high level of economic activity or to stable prices. The Council might determine that, as a result of actions taken or not taken in the past, some decline in business activity or some inflation in prices is beyond the effective capacity

of available or conceivably obtainable stabilization measures. I doubt, for example, that any realistic deployment of stabilization measures in 1946-47 could have prevented some inflation. The seeds of inflation were sown long before. Similarly, the seeds of recession may be sown by past failure to control the excesses of the boom. Or the Council's projection might reflect the judgment of government as a whole that other national policy considerations, such as national defense, take priority over stabilization policy and that completely successful stabilization is therefore precluded. But apart from such situations, the "conditional economic projection" should point toward a satisfactory level of production, employment, and purchasing power. This is the mandate of the Employment Act.

I dwell upon this point because I have encountered two attitudes toward the forecasting activities of the Council of Economic Advisers, both of which I believe to be in error. One is the impression, because the Council's projections do point to good levels of economic activity, that the Council is nothing more than a propaganda agency, trying to talk us into prosperity. This attitude arises in part from a lack of candor in the preliminary or initial analysis of economic prospects by the Council. But also, and perhaps more fundamentally, it arises from a failure to recognize the character of this conditional economic projection—that it is not a "cold turkey" forecast, but rather a statement of what should eventuate if appropriate policy changes are made.

The second misimpression is the notion, sometimes subscribed to within the walls of the Council as well as elsewhere, that the requirement for a reasoned but optimistic conditional economic projection, as the end result of the forecasting and policy analysis process, necessarily precludes a frank and forthright statement of the unfavorable aspects of the economic outlook in the course of the analysis. This is admittedly a delicate issue. The Council is presumably an authoritative forecaster. It is authoritative, not only because of the presumed competence of the members of the Council and its staff and because it has approximately full access to all available information, but also because it is a part of the presidency—because it plays an important role in determining what government policy shall be and therefore to some extent is in a position to make its forecasts become true. Because it is thusly authoritative, its pronouncements carry weight in the public mind. The "feedback effect" of a pessimistic analysis therefore could conceivably be considerable. In light of this circumstance, can—or should—the Council be completely frank and forthright in its preliminary analysis?

As I see it, there are two aspects to the answer to this question. First, in spite of the admittedly authoritative character of the Council's forecasts, it is my experience that officials of government typically

exaggerate the public impact of what they say. (Occasionally they underestimate, as in the case of Mr. Wilson's dogs, but this is the exception.) The belief that a frank, preliminary analysis of all factors involved, including unfavorable elements, will necessarily have adverse effects rests on the implicit assumption that businessmen and others who make important economic decisions have little or no knowledge of what is likely to happen beyond that which is told to them by government. This view seriously underestimates the economic literacy of Americans, notably businessmen. They form their judgments on the basis of a variety of economic information, of which government pronouncements are only a part. The feedback effect of a frank analysis, in the business community at least, is a moderate one at most.

Second, it is entirely possible to assess squarely the unfavorable elements in the business outlook in an unsensational and matter-of-fact manner which will minimize any feedback effect. True, if an *Economic Report* were to open with the shocking words, "A serious depression is impending unless drastic action is taken," the feedback effect might be enormous. But a report which calmly and dispassionately analyzes the many facets of the economic outlook, the unfavorable along with the favorable, need not arouse excitement. Indeed, failure to recognize unfavorable elements, which are clearly apparent to others, may well be destructive of public confidence by suggesting that government does not know the economic facts of life and is therefore unprepared to cope with these unfavorable developments. In my judgment, the most confidence-creating course of action is a frank and highly objective preliminary forecast coupled with a policy prescription based on that preliminary forecast adequate to insure realization of our stabilization objectives.

IV

The character of a forecast, or economic projection, is inevitably influenced by the method employed in making the forecast. Forecasting methods based on single or exclusive causes, whether they be sun spots, weather, or changes in the quantity of money in circulation, have now been generally and properly thrown into the discard. So have techniques based on an assumption of rhythm in business fluctuations. One could scarcely have lived through the last twenty-five years and still adhere to the theory that business conditions can be determined by extrapolating one or more sine curves.

Another forecasting technique deserves more attention, if only because it is a technique which apparently is looked upon with some favor in the offices of the present Council of Economic Advisers. This is the technique, developed most thoroughly at the National Bureau of Eco-

nomic Research, of identifying certain economic variables which, in the past, have tended to lead general business fluctuations, and of watching these series closely for signs of an impending turn. Mr. Geoffrey Moore has identified eight such series which, I am sure, are familiar to all of you.

This technique of forecasting has an appeal because of its statistical objectivity, and it unquestionably has certain usefulness, particularly for calling the turn on short-run fluctuations. As a sole or even primary instrument of stabilization planning, however, it suffers from four serious defects which, I am sure, the National Bureau fully recognizes. First, the technique is largely symptomatic. It is heavily dependent upon the assumption that certain structural relationships within the economy will persist into the future. By implication it assumes, for example, that the relationship between commercial and industrial construction contracts awarded to total output is impervious to changes in industrial technology, or that the relationship between so-called "sensitive" prices and prices in general is not affected by shifts in the composition of national output. Second and more important, because it is symptomatic, there is nothing inherent in the forecasting process which throws light on the fundamental operative causes of economic change. The technique itself, therefore, provides no indication of needed remedial action.

Third, by focusing attention on turning points, the lead-and-lag technique may lead the forecaster into paying insufficient attention to the probable level of economic activity. A case in point is the degree of satisfaction with economic prospects expressed in the January, 1954, *Economic Report,* apparently based on indications that no major downturn was probable, in spite of the fact that for several months prior to that time, and since, business activity failed to grow in proportion to increasing productivity and an increasing labor force. And, fourth, it is short-run forecasting. At best, it can predict only a few months into the future. Such short-run forecasting is, of course, highly useful. But the much greater need is for longer run projections which permit a more fundamental diagnosis and a more effective use of long-lead-time stabilization techniques.

A much more useful and promising approach to forecasting for economic stabilization is income and product model building—a technique which can be traced back to 1932, and perhaps even earlier, but which has been practicable only since the expansion by the Department of Commerce in the late thirties of their national income and product accounting series and which has been experimented with on an extensive scale only in the past ten or fifteen years.

The technique is now well understood and rather widely used. Three outstanding recent examples are *Markets after Defense Expansion,*

published by the Department of Commerce, Gerhard Colm's *The American Economy in 1960,* and *Potential Economic Growth of the United States during the Next Decade,* by the staff of the Joint Committee on Economic Report. All three of these studies, incidentally, disclaim being forecasts. To the extent, however, that the projections of demand made in each of these studies are supposed to be realistic and feasible potentialities, given proper public policies, they come close to being forecasts of the type I have in mind.

One important advantage of income and product model building is that it encompasses the entire gamut of economic activity. The method itself requires the forecaster to consider, in as much detail as is practicable and necessary for the purpose, all of the components of the totality of demand. The completeness of the analysis is limited by the sufficiency and accuracy of the raw material, factual and theoretical, which is fed into the model, not by the model technique itself. For the same reason, model building tends to prevent the forecaster from placing undue emphasis on one particular variable. The mere act of listing all of the components of gross national expenditure and assigning reasonable values to them subdues the temptation to select one dramatic one, such as residential construction or military expenditures, and attach exaggerated significance to it.

A related advantage of income and product model building is that the technique requires the projection not only of demand for total national output but also of potential supply at given levels of employment. It forces the forecaster to recognize and make allowance for the effects of growth in the labor force, increasing labor productivity, changes in the labor participation rate, the average work week, etc. Failure to do this can easily lead, for example, to complacent conclusions to the effect that 1954 is "our second best year," which it definitely is not when measured in terms of potential output. This is a particularly relevant consideration as regards forecasting by the Council of Economic Advisers. The Employment Act requires the President to set forth levels of production, employment, and purchasing power needed to carry out the policy of the Act; that is, realizable output goals against which performance can be measured. The *Economic Report* of last January failed to define these goals. Such goals, whether they be maxima or minima, optimistic or pessimistic, are an essential element in income and product model building.

Perhaps the most important advantage of income and product model building is that it integrates aggregative economic theory and the forecasting calculation. Economic analysis becomes a part of the forecasting process and not supplemental to it. In essence, model building is translating macroeconomic theoretical concepts into numbers, past and prospective. Theoretical concepts as to functional relationships, such as

the relationship between income and saving or between growth in real disposable personal income and business investment expenditures, can be put into appropriate combinations of numbers in the model. Moreover, prospective changes in these functional relationships can be reflected in the model. They are not necessarily assumed to be fixed, as in the case of the leads-and-lags approach.

Model building, however, also has its disadvantages and limitations. One disadvantage—which is not inherent in the method but which is usually present in actual application—is a temptation to focus on highly aggregated magnitudes at the expense of detail. This disadvantage, I think, has been a more real one to the econometricians who have attempted to reduce the relationships involved in the model to a finite system of equations of manageable proportions than it has been to those who use the nonmathematical or quasi-mathematical approach to model building, where a much larger number of variables can be handled in an approximate, if nonalgebraic and inexact, fashion.

A second disadvantage in model building—which again is not inherent but which I believe is usually present—is some tendency toward a pessimistic bias. Projections of demand include demand for those already existing goods and services which can be estimated from data on consumer stocks, sales, apparent trends in consumer habits, etc. But they also include the demand for the new and the unknown. It is easy to see and predict the decline of the old but is extraordinarily difficult to foresee the rise of the new.

A third practical difficulty is that the process is inevitably slow and laborious, and it is scarcely a one-man job. The voluminous data required for a well-reasoned projection are slow in becoming available. The time required to analyze the data and all of the major interrelationships involved and to revise preliminary assumptions and subsequent calculations is considerable. The slowness of the technique, on the other hand, is in some respects an advantage. It prompts the analyst to concentrate on fundamental changes in economic activity rather than on the most recent wiggle in this or that curve. What is lost in the way of currency of forecast of very short-run fluctuations may well be more than compensated for by less ephemeral and more thorough analysis of the intermediate and longer run fluctuations which constitute the important economic stabilization challenge.

V

This leads me to the second main thesis of my paper, as follows: Forecasting techniques have advanced to the point where they are beginning to provide a reasonably reliable basis for economic stabilization policy making. I believe that much of the pessimism regarding the potentialities of forecasting, to which I referred earlier, is exaggerated

or outdated. I am not suggesting that we have the problem solved, or that anything resembling perfect forecasting is possible. Rather, I am suggesting that it is possible to develop income and product models which, supplemented by leads-and-lags and perhaps other analyses, show the general direction of economic change, its approximate though not exact timing, and at least a rough gauge of the magnitude of that change. And I am suggesting, further, that such projections provide a sounder basis for stabilization policy making than do intuitive judgment, extrapolation of the *status quo*, or action after the fact. Let me indicate briefly some of my reasons for this cautiously optimistic view of forecasting.

First, it hardly needs to be said that great progress has been made toward a better understanding of the process of economic change in the last two decades. This is not mere breast-beating on behalf of the economics profession. A healthy scientific skepticism toward our profession is all to the good, and we should remind ourselves frequently of past failures of economic analysis, especially of those of the late twenties. But skepticism and self-abnegation can be carried too far. It is a plain fact that economic science has made great strides in the past twenty years or so. Thanks largely to the revolution in economic thinking touched off by the depression and by the *General Theory*, we have added enormously to our supply of tools of economic analysis. We are in a much stronger position to attack and solve economic problems than we were a short generation ago.

Second, one of the main exogenous variables of former years is no longer so unpredictable: government policies affecting economic activity. This may be attributed partly to the commitment of the Employment Act, but it is also due to the clearly evident increase in economic understanding on the part of responsible officials of the government—notably members of the Congress.

Third, the adequacy of data needed for forecasting is gradually improving. Although much remains to be done, recent years have witnessed a steady improvement in the quantity, quality, and timeliness of economic statistics. The series on manufacturers' new orders deserve special mention in this regard. And beyond this general improvement, one statistical innovation of great signifiance has been made: the application of scientific sampling techniques to the analysis of intentions to spend, such as the Commerce-SEC and McGraw-Hill surveys of business investment anticipations and the consumer surveys conducted by the Michigan Survey Research Center for the Federal Reserve and certain private organizations.

These surveys are relatively new. They suffer from certain inherent sources of error, including: the fact that many respondents, even large corporations, frequently make only very tentative plans as to future

actions; and individual responses inevitably involve an implicit forecast as to general economic developments, which may prove to be wrong. The surveys have not been tested by a major decline in business activity. Nor has enough work yet been done to develop them to their maximum usefulness. Experience to date, however, is encouraging. The Commerce-SEC projections of total expenditures for new plant and equipment have corresponded closely with actuals, both as to direction of change and magnitude, in every year except 1950, and the industry-by-industry projections have been accurate as to direction of change in a high percentage of instances. (See Louis J. Paradiso's paper on "Economic Projections by the U.S. Department of Commerce," scheduled for publication in the *Proceedings* of the American Statistical Association meetings of September, 1954.) The Michigan surveys of consumer attitudes toward purchases of durable goods have accurately predicted direction of change and have not been too far off as to magnitude. (See, for example, Rensis Likert's statement in *Hearings* before the Subcommittee on Economic Statistics of the Joint Committee on the Economic Report, July, 1954, pages 288-295.)

As experience with these surveys increases, it should be possible to improve them further and to develop improved techniques for compensating for inherent sources of error particularly if better information can be obtained as to the character of implicit forecasts and as to degree of intention; i.e., the firmness of the planned expenditure. Some progress along these lines has already been made.

If I may continue to digress for a moment, I would like to mention briefly two other improvements in data which would make a further contribution to our ability to forecast. One of these would be the regular publication by the Department of Commerce of quarterly, seasonally adjusted estimates of gross national income broken down on an after-tax, after-transfer basis which would be comparable with our present so-called "gross national product" series. What I have in mind in this regard is the kind of arrangement of data which used to be published semiannually by the Council of Economic Advisers under the title, "The Nation's Economic Accounts." In spite of statistical imperfections, this tabulation is an extremely useful analytical tool. Unfortunately, it now survives only in occasional publications of the Joint Committee on the Economic Report, in a vestigial annual appendix table in the *Economic Report of the President,* in a chart with no numbers attached in *Economic Indicators,* and in Gerhard Colm's work at the National Planning Association.

Second, we need better information for measuring and projecting changes in the economy's productive potential. We need quarterly series showing man-hours worked in total and in the nonfarm private, the agricultural, and the civilian government sectors of the economy. And

we need more comprehensive and accessible measurements of productivity and more research into the causes of productivity increase.

There is one facet of the productive potential about which my own thinking is not yet clear and which there is not time to develop in this paper. Three years ago the Paley Commission focused our attention on the proposition that the real unit costs of the material and energy inputs into the American productive process may have finally emerged from their secular decline and may now be predominately on the increase. Ever since then, I have had the uneasy feeling that our rather facile projections of past trends in real output per man-hour—particularly the longer run projections—do not give adequate consideration to this possibility.

My fourth and final reason for optimism—to return to the main stream of my argument—is the impression, which I cannot prove, that by the pragmatic test forecasting has fared much better in recent years than it did some years ago. The projections of the Council of Economic Advisers, though frequently ambiguous and hedged about, have been essentially accurate, save only for the misfire of January, 1949. The projections following the Korean invasion were generally good, in spite of the complications injected by strong psychological factors ("Is This World War III?") and in spite of exaggerated estimates by the military as to anticipated levels of defense expenditures. The model builders, almost unanimously, forecast the current—or should I say recent—recession, at least as to timing and, with a good deal of trepidatory hedging, as to magnitude also.

In spite of this improved record, there is still widespread reluctance to bring models out into the open. There have been a few exceptions—notably the reports of the staff of the Joint Committee on the Economic Report under Grover Ensley's direction. The Congressional members of the Joint Committee deserve commendation for encouraging these studies. But these are exceptions. In the main, there is still an air of black magic about the business of forecasting. The time has come, I believe, for serious and responsible forecasters, especially those in authoritative positions, to open their books to the public, to state specifically their assumptions as to exogenous factors, to describe fully the techniques and logic by which estimates are calculated, and to develop preliminary projections in the form of quantitative models. But I would like to emphasize again that in forecasting for economic stabilization purposes, the number work is only the beginning of the process. More than mathematics, whether it be higher or lower mathematics, is required in forecasting for economic stabilization. The important part of the job is the application of judgment and understanding of both economic process and political process to the identification of those changes in economic policy, private and public, which will lead to high employment and stable economic growth.

POLITICAL ELEMENTS IN FULL EMPLOYMENT POLICY

By Stephen K. Bailey
Princeton University

Earlier in this century, a distinguished economist wrote a book the last chapter of which was entitled, "If I Were Dictator." It was a glowing account of what economic measures would save society if only politicians were not around to louse things up.

My theme today is built around the dismal forecast, now widely shared by most economists, that politicians are likely to be around for some time to come. Let me hasten to add, however, that there are stabilizing factors at work and that the secular trend is bullish, although the rate of development may not be great enough to guarantee in the short run the maximum utilization of all the resources of the American Economic Association and the American Political Science Association.

It is ten years, almost to the day, since a group of economists, political scientists, and politicians sat around a table on Capitol Hill and drafted a so-called "Full Employment Bill." In the eyes of history, this temporary confluence of professions may have been of more importance than the Employment Act itself. For one of the central problems before both economists and political scientists is how to make politicians as smart as we are and (if I may be pardoned a heresy) vice versa. This is what Lord Macaulay had in mind when, referring to currency reform in the reign of William II, he said: "It would be interesting to see how the pure gold of scientific truth found by the two philosophers was mingled by the two statesmen with just that quantity of alloy which was necessary for the working."[1]

The problem is not new. What is new is the degree of our own self-consciousness that an interdependency exists. One of the salutary results of the Employment Act has been the forcing together of professional economists and professional politicians on a scale hitherto unknown in this country. In Mr. Nourse's felicitous expression, "the research division, the engineering division, and the sales division," have been constrained to sit down together. Even if Mr. Nourse himself found this confluence at times an unhappy one, he has enormously increased our sum of knowledge about the pitfalls of this necessary collaboration.

I do not wish to attempt a detailed summary of the obvious. You are more fully aware than I of the political elements in full employment policy. In fact, some of the most sophisticated writing in this field has been done by economists. I need only refer to the writings of Mr.

[1] Quoted in C. H. Hankin, *The Mental Limitations of the Expert* (India: Butterworth & Co., Ltd., 1921), p. 27.

Blough and Mr. Nourse to make my point. They, and others, have listed the tough ones.

But purely as a preliminary catechism, let me recapitulate a few major points:

1. America is a vast and highly pluralistic society. There is no hand, seen or unseen, which is capable of homogenizing all of the diverse political and regional appetites of our country into a uniform, Grade A public interest. This frequently leads to shifting compromises and "second bests" in economic as in most other policies.

2. Full employment in a free society is an aggregate concept. The constituent pressures on a congressman are often highly "unaggregate."

3. Politicians, like some other people who shall remain nameless, occasionally differ on the subject of what policies actually will produce a condition of full employment. The difference between politicians and others in this respect is that if politicians guess wrong, they run the risk of losing their jobs. They have a tendency, therefore, to do a very cowardly thing: they hedge.

4. There is in America a tradition of what Burt Marshall has called "serendipity." Serendip is an ancient term for Ceylon. Mythology recalls that there were once three princes of Serendip. In Mr. Marshall's words, these three princes were "special favorites of benign fortune. Things never worked out as the princes planned them, but they always worked out remarkably well, nevertheless, and the princes went through life blessed with unintended and unforeseen happy consequences."[2] The principle of serendipity accounts for whatever truth there is in Grover Ensley's claim that, on the whole, Congressional action in the economic field during the past ten years has been sounder than the advice of economic experts. Serendipity makes some congressmen smug —more smug, perhaps, than is warranted by an uncertain future.

5. The phrase "full employment policy" seems to imply a consistent and co-ordinated federal effort. That co-ordination is made remarkably difficult by the extraordinary jogs in Pennsylvania Avenue from 17th Street, N.W., to 2nd Street, S.E. Twists of institutional jealousies and prerogatives in the tax and appropriations lanes alone make driving hazardous and destinations uncertain.

6. Even within the Executive Branch, Departments like Agriculture, Labor, Commerce, Interior, Treasury, and the Veterans Administration do not always see eye to eye with each other—or with the President. And there is of course the problem of independent and quasi-independent agencies like the Federal Trade Commission, the Interstate Commerce Commission, the Federal Reserve, and Mr. Wright Patman.

7. Even within the Executive Office of the President, there is no

[2] Charles Burton Marshall, *The Limits of Foreign Policy* (Henry Holt & Co., 1951), p. 46.

assurance that all those who should, actually will meet together in the lobby of the Sherman Adams Hotel.

8. State and local governments make decisions about spending and investment on the basis of political considerations frequently ignored by department heads and presidential advisers in Washington. I happened to be Mayor of Middletown, Connecticut, when Mr. Humphrey, with the help of some friends in the Federal Reserve, slammed on the brakes in the spring of 1953. Fortunately for Middletown (and perhaps for Mr. Humphrey and the United States), his foot slipped. We would have built the schools anyway, but an interest rate of 1.90 is a lot easier on the books and the ballots than 3.25. And never underestimate the power of local officials. Representative Seeley-Brown is a Republican and I am a Democrat, but I called him Seeley and he called me Steve.

9. State and national elections come periodically. It is becoming increasingly obvious that a "healthy readjustment" is easier in odd years than in even.

10. Finally, the apocalyptic spectrum known as international relations is in the hands of politicians, here and abroad. Full employment policy is mightily conditioned by international events, even if the reverse is also true.

These are some of the major political variables which stand between the scientific economist and consistent economic policy. They are what I would call the centrifugal forces in our government. The search of both economists and political scientists in the past two decades has been for countervailing, centripetal forces which might increase the rationality of decision making in the field of economic policy. We have a long way to go, but I think we ought to count our blessings. Progress has been made, and the progress is impressive.

The first centripetal force has been in the field of economics itself. Through brilliant analytical work, the economics profession has narrowed its own areas of disagreement. There are few economists left, for example, who would argue for a tax rise in a major depression, as Roosevelt did. The crystallizing orthodoxies of the economics profession make their way into both branches of the federal government, and after a slight delay have an enormous impact upon policies. As Lord Keynes wrote so brilliantly:[8]

> The ideas of economists and political philosophers, both when they are right and when they are wrong, are more powerful than is commonly understood. Indeed the world is ruled by little else. Practical men, who believe themselves to be quite exempt from any intellectual influences, are usually slaves of some defunct economist. Madmen in authority, who hear voices in the air, are distilling their frenzy from some academic scribbler of a few years back. I am sure that the power of vested interests is vastly exaggerated compared with the gradual encroachment of ideas.

[8] J. M. Keynes, *General Theory of Employment, Interest, and Money* (London: Macmillian & Co., Ltd., 1936), pp. 383-384.

There has been a heartening increase in agreement among the members of the Joint Committee on the Economic Report during the past six years, and I submit that this increase would have been impossible without the establishment of prior agreement within the economics profession itself.

The second centripetal force has been at the level of executive organization. The tentative, and almost accidental, character of Executive Branch interest in problems of economic stabilization forty years ago is reflected in a letter written to President Wilson by his Secretary of Commerce dated May 7, 1913. The letter reads as follows:[4]

> Sir: There is much practical wisdom in the suggestion made by you to Secretary McAdoo yesterday, respecting the advancement of public works under present conditions, that I venture to add a word in the same line.
>
> The point of attack in the matter will not be with the executive departments. These, inspired by you, will act quickly when authorizations and appropriations allow. It is the chairmen of the two appropriations committees who control the situation. I would suggest a conference, at early convenience with these chairmen and with Mr. Underwood, and others if you prefer, to point out to them the practical value to us now (not at a future date, but today) of such appropriations as will permit the progress during this summer and fall of contract work as fully as possible.
>
> The Department of Commerce has asked appropriations for lighthouse and other work already authorized, aggregating something over a million dollars, at many different points. They are no more needed than other public works, but they would add to employment and the distribution of funds, and if appropriations were deferred to the next session of Congress a year would be lost, during which much might happen. Practical common sense would seem to indicate the wisdom not only of appropriations for needed public works, but the political expediency of having those appropriations quickly, for the reason so cogently stated by the Secretary of Labor yesterday.
>
> Respectfully,

In regard to Executive-Legislative relationships, this letter is as hot as tomorrow's headlines. Many of the problems it raises are still unanswered. But there have been major changes in the institutional mechanisms for apprising the President of what he can or should do. The great landmarks in this development have been, of course: the Budget and Accounting Act of 1921; the Reorganization Acts of 1939, which established the Executive Office of the President; the Employment Act of 1946; the National Security Act of 1947; and the subsequent administrative additions and changes which have been made within the Executive Office framework itself. The Executive departments and agencies still ride off in a variety of directions; strategic and tactical moves in relation to Congress are still handled gauchely at times; but the clearance and advisory mechanisms in the Executive Office have markedly increased the chances that policy free-wheeling will be a matter of political choice not of staff default. And these mechanisms are constantly being refined. The reconstitution of the Council of Economic Advisers in 1953, for example, established an Advisory Board on Economic Growth and Stability under the chairmanship of Arthur Burns.

[4] Letter from William C. Redfield, Central Records of the Department of Labor in the National Archives, 16:71.

This interdepartmental board includes representatives, at the under or assistant secretary level, of Treasury, Agriculture, Commerce, and Labor. It also includes a member of the Board of Governors of the Federal Reserve System, the Assistant Director of the Bureau of the Budget, and Dr. Gabriel Hauge of the White House staff. There is no necessary magic in interdepartmental committees. Washington probably suffers from too many of them. But in this particular case, an interdepartmental advisory committee may be an extremely useful educational and policy co-ordinating device.

A third series of centripetal forces have developed in Congress and in the structure of political parties. The Legislative Reorganization Act of 1946 was not an unmixed blessing in this regard, but it did result in the establishment of Majority and Minority Party Policy Committees in the Senate, it did cut down on the number of standing committees, and it did focus attention on the problem of diffusion in Congressional activity. The very existence of the Joint Committee on the Economic Report and the Joint Committee on Internal Revenue Taxation with their respective staffs indicates that Congress is aware of the need for a more unified appraisal of fiscal and economic programs.

Both Republican and Democratic National Committees have increased their research services to Congress and have sincerely tried to find common denominators of agreement on economic issues within their respective parties.

Regularized channels of communication between the President and the Congress have increased in quality and quantity during the past two decades. I refer not only to the care now taken in the preparation of the three annual presidential messages—on the "State of the Union," the budget, and the *Economic Report*—but to the new liaison status given to the Vice President, the weekly meetings between the President and his Congressional leaders, and the more systematic use of department heads in defending the President's program before the Congress.

These are all encouraging signs. But, unfortunately, centripetal mechanisms, no matter how carefully they are designed, are not enough. As J. S. Mill once said: "In politics, as in mechanics, the power which is to keep the engine going must be sought for outside the machinery." In the final analysis, economic stabilization like any other policy goal depends upon the system of value priorities and the political skills of those who wield political power. No matter where we turn in government we find that economic goals are conditional. Man does not live by bread alone. The goals of physical survival and of freedom itself are not necessarily in conflict with, but they are certainly antecedent to and higher on the value ladder than any circumscribed economic goal—no matter how desirable. To get at these value interrelationships we need

a lot more than a Council of Economic Advisers or a Joint Economic Committee. We need political leadership at both ends of Pennsylvania Avenue—leadership which is capable of performing the highest task of statesmanship: the mobilizing of power behind articulated goals. In the kind of governmental system we have in America, this is an extraordinarily difficult assignment. Lines of responsibility and accountability are not clear cut. The vast and frequently competing congeries of power represented by interest groups in our society are not easily moralized or even contained. The shifting sands of public opinion and the swiftness of changing events make the very task of goal setting and political implementation extremely hazardous. And yet the mobilization and harnessing of political power is the only master key to the development of consistent programing in the economic or any other field.

This puts an extraordinary burden upon the President of the United States. Mr. Truman realized this when, without prophetic insight as to his successor, he stated that the President's desk is like a general's. Truman outlined what he called the five vital steps of strategy: (1) estimate your own resources; (2) estimate your enemy's resources; (3) form a judgment as to what is to be done; (4) implement that judgment with a plan; and (5) persuade your leaders of the value of that plan, and mass your forces for the attack.

This is almost a perfect description of what most presidents have not done or have done badly. Presidential leadership means what human leadership has always meant: taking account of multiple forces and interests in a more subtle and forceful way than traditional, formal procedures generally permit. Possibly the greatest single weakness of the present administration is its faith that institutional arrangements, secretariats, and rationalized divisions of labor in the Executive Branch are by themselves adequate to deal with the complex and diverse value configurations of our national polity. The setting and dramatizing of goals, especially in the economic field, have been intermittent, often contradictory, and almost casual. It was not until the exigencies of a political campaign forced the issue that the President was willing to set economic goals for longer than a month or two in advance. I only hope and trust that this reluctance to perform the highest function of presidential leadership was not due to staff suggestions that because forecasting is not economically "scientific" the President should ignore his prophetic role. If this were the case, it only lends fuel to the fire of my own conviction that untainted, professional, scientific economists belong back in a dark corner of the Budget Bureau, not at the level of direct advice to the President. However hard it may be on the egos of some economists, the Council of Economic Advisers was not set up to please the American Economic Association. The Employment Act is

quite clear about the policy functions of the Council. The Act states explicitly that each member of the Council shall be a person who, and I quote, "as a result of his training, experience, and attainments, is exceptionally qualified to analyze and interpret economic developments, appraise programs and activities of the government in the light of the policy declared in Section 2, and *to formulate and recommend national economic policy* to promote employment, production and purchasing power. . . ." (Italics supplied.)

The Council, in short, was established to help the President perform his goal setting function, to help him as a sorter of values, and to help him in his role as a mobilizer of political power. This makes the Council, inevitably, a participant in the political process, not an adjunct thereto. The Act implies that members of the Council should be something more than economists, that they should be in tune with the value premises of the President, and that like the President they should be politically expendable with changes in administration.

I am aware that this is a controversial subject among economists—and that I am taking an unpopular position. But I must as a political scientist state my position with some emphasis. I do not believe that economists have any right to participate in high policy making without running the risks of political involvement and political compromise. Those who will not play unless they are guaranteed immunity against politically-tailored value commitments remind me of the early Fabian socialist, Joseph Burgess, who refused to compromise on some issue during a general election and thereby lost his seat in Parliament. George Bernard Shaw complained bitterly as follows:[5]

> When I think of my own unfortunate character, smirched with compromise, rotted with opportunism, mildewed by expediency . . ., putrified by permeation . . . I do think Joe might have put up with just a speck or two on those white robes of his for the sake of the millions of poor devils who cannot afford any character at all because they have no friend in Parliament. Oh these moral dandies, these spiritual toffs, these superior persons. Who is Joe anyhow that he should not risk his soul occasionally like the rest of us?

If an economist wishes to limit his activities to objective economic analysis, he has a perfect right to do so; but that right should be exercised about three steps or three blocks removed from the President. What some economists call the "scientific" function is an indispensable function in modern government, but it is a totally different function than that prescribed for the Council of Economic Advisers by the Employment Act. If the Employment Act had established the Council as a Supreme Court of Economic Truth, it would have created an administrative monstrosity. The Presidency creates a magnetic field which structures everything it touches with the electricity of politics. An economist has no option. He must either escape the field completely,

[5] Hesketh Pearson, *G.B.S.* (Harper & Bros., 1942), p. 156.

or he must be drawn into the magnetic orbit. The economics profession cannot have it both ways. It cannot claim political immunity for Mr. Burns and at the same time ignore the fact that he made a major public speech in Detroit, Michigan, two weeks before a national election.

With all due respect to Mr. Nourse, the tortured early history of the Council was in part his own making. He attempted to make the Council into something it was never intended to be and, at its peculiar level, never can be: an oasis of pure economic science. Mr. Burns, with rare and notable deviations, has doubled in spades. This perspective has tended to make the Steelmans and the Hauges, the Snyders and the Humphreys the true economic advisers to the President and has stringently limited the Council as a true policy arm of the Chief Executive. Mr. Keyserling may have carried the logic of his own position and personality to unnecessary extremes, but this was in part an understandable reaction to the sincere but pristine myopia of his distinguished predecessor.

The present sorry and bitter hiatus between the Council and the Joint Committee is more than a matter of personalities. It is a direct outcome of a misreading of the proper role of the Council. There may be good tactical reasons for keeping the Council away from public hearings before Congressional committees, but there is every reason in the world to keep constant and friendly informal contacts rolling between the Council and the Joint Committee. There is every reason, that is, if both the Council and the Joint Committee are policy-oriented. If the Council is not policy-oriented—if it conceives of its chief function as that of adding up freight car loadings to give the President a Monday morning statistical summary of current indices and short-run projections—the Joint Committee is inevitably left high and dry as a potential weapon of presidential influence in the field of economic policy.

Goal setting, although the supreme task of a President, is not worth much unless there is political follow-through. In the economic field, unless the Council helps—at least covertly—in this follow-through, the President must depend upon *ad hoc* expedients which lack both the strength of considered strategy and the ideological force of economic sophistication. A little recent history is perhaps germane at this point.

In November, 1947, the Council of Economic Advisers reported to the President and the Cabinet that the then inflationary dangers were serious to both the short-run and the long-run stability of the economy and suggested a ten-point legislative program to handle the situation. The ten-point program was submitted to a special session of the Eightieth Congress with neither proper bill drafts nor Executive Branch clearance on testimony to back it up. As far as I can judge from a study

of the records, there was not even a suggestion of strategic thinking about pressure groups and Congressional support. In January, 1948, the President reiterated this demand for anti-inflation legislation in his "State of the Union" message. Again there was no conscious strategic planning in the Executive Office or elsewhere for the active mobilization of a working coalition to get results. In the summer of 1948, President Truman called a special session of Congress and again submitted an anti-inflation program. Virtually the only concession to strategic thinking this time was a hurried call to Paul Porter to testify, after a superficial briefing, before a Congressional committee on behalf of the President's program.

After the November elections and in preparation for the Eighty-first Congress, the President appointed Dr. Nourse, then chairman of the Council of Economic Advisers, as head of an *ad hoc* cabinet committee to work out an omnibus economic stabilization bill. In January, 1949, after much of the technical preparatory work had been finished, Secretary of Agriculture Charles Brannan took on the job of developing agency and Congressional support for the bill. Here, after fifteen months of virtual futility, was the first serious attempt to look at the economic stabilization program in terms of building effective consent behind it. But even here, the strategic planning was pitifully inadequate.

All this adds up to the fact that the development of a consistent economic policy in the federal government cannot even be approximated without the central formulation of a political program and the mobilization of a successful coalition of power to carry the program through.

I cannot conclude without pointing out that presidential leadership —even with the aid of a policy-oriented Council—is only one facet of this problem. Congress must respond with a more consistent power focus than it has developed up to now. That focus can never be as clear as the President's, for the kaleidoscopic representative function of the Congress interferes—and probably should interfere. But the tolerances for programmatic anarchy should, in my estimation, be narrowed. Insofar as the force of ideas is important here, the Joint Economic Committee even now performs a significant function; although that function could be strengthened if a more sophisticated provision were made for a "legislative clearance" liaison between the members and the staff of the Joint Committee on the one hand and the members and staffs of the standing committees dealing with major economic legislation on the other. It is possible that a joint economic-budget committee, as suggested by Mr. Colm, might help in the development of more consistent economic policies; although, if the Congress went that far, I think that I should prefer a joint committee on the state of the

union which might operate each year for not longer than three weeks and whose sole job it would be to hear testimony on the interrelationships of the three presidential messages.

But again, the real key here is not minor institutional changes to help spread the cold light of reason. The Spanish writer, Unanumo, thinking of Goethe's dying words, "Light, light, more light," declared passionately, "No, warmth, warmth, more warmth; for we die of cold not of darkness. It is not the night that kills but the frost."

The great job of the Congress and of our political parties is to build responsible communities of interest around the major value goals of our society—not to reflect but to refract and moralize the divisive pressures in our democracy. Whoever, through personal leadership or through refining the administrative and political instruments of government, is able to develop more cohesive and responsible power behind more coherent and intelligently constructed programs will have solved the key political elements in full employment policy.

DISCUSSION

SOLOMON BARKIN: Both papers reinforce the demand that the Council of Economic Advisers abandon its aloofness and assume direct responsibility for making economic forecasts for the short run and evaluations of the adequacies of our short-run and long-run economic performance in terms of the primary objectives of the Employment Act of 1946. The Council was created to help realize a high-employment economy. Its members must help the Chief Executive formulate policies to attain this goal. Despite the determination of both the Council and the President of the United States to avoid the test implicit in the Act, the very exigencies of our political life compelled their acceptance during the last few weeks of the political campaign. They abandoned comparisons between current and past performance and admitted that the real measure of our economy is its ability to realize the full potential of growth and utilization of man and resources. This turn gave many of us confidence that our national government will more conscientiously seek both economic stabilization and growth.

Economists, both in and out of government, must undertake to make forecasts of future developments, analyze the implications of current economic institutions, and elaborate on the effects of alternative policies or plans. Their occupation involves the organization of past economic events into orderly patterns which suggest a sequence of occurrences, a time relationship, and a series of effects. Seeking to understand the past and the present, they cannot reject the responsibility for forecasting and projecting the future, for they will then be denying the utility of their knowledge and the continuum of human affairs within the area of their competence. Neither of these positions can be stoutly defended by economists serving active economic or public agencies. Their responsibility is to provide their principals with the insight and knowledge, no matter how carefully they define their assumptions and express the limitations of their own efforts.

The economist must concern himself with short-run, intermediate, and long-run forecasts. The objectives are stability and growth at all times and throughout an entire period. To minimize the short run is to overlook the political implications of temporary periods of distress or the disaster which may befall us in the long run from short-run reverses. Professor Turner properly adds his voice to the many who have cautioned against mechanical techniques for forecasting. However scholarly the source or the auspices, one must be suspicious of the results. They have proven treacherous at critical points. The techniques overlook the familiar observation that however similar the future is to the past, it is necessarily different. Structural and institutional changes are constantly occurring to alter performances. Governmental and political factors make obsolete older relationships. Laws are passed and institutions are created to change the old, so that new conditions will be born. The past, therefore, is a defective guide for the future.

The lag-and-lead technique for economic forecasting is built upon such past performance. It may be helpful in signaling short-run economic turns,

but it cannot be used to predict the length or intensity of cycles. In the hands of the astute student of economic developments it is useful for analyzing economic events. The trade-union economist must include them in his battery for study, because he must be able to preceive the downturn long before it is evident to the community at large. His responsibility is to alert trade-union leaders and the government to the need for corrective action.

The defects of the mathematical projection are made evident by a study of the shortcomings of a commonly used procedure for forecasting economic trends in the textile industry. It is assumed by some textile economists that the two-year cycle of textile activity is still characteristic. But in fact, significant changes in inventory practices of apparel manufacturers and retailers and the lively competition among apparel items resulting from the revolutionary changes in our clothing habits have reduced the influence of this inventory factor. In this era of innovation, past relationships are being strikingly modified. Management itself is more keen about and anxious to introduce new production methods and final products. Suburban communities and the new patterns of living flowing from full employment and higher living standards are changing the propensities for consumption of different types of goods. Mechanical projections of prewar or early postwar experiences are likely to lead to deceptive results.

The increased use of the projection technique is to be applauded, but it should not be described as a forecasting tool. It is primarily an analytical procedure for examining the implications of current institutions, usually for some point in the future, and for spelling out the probable effects of specific policies. It is most useful for studying the steps necessary to realize such specific goals as are spelt out in the Employment Act of 1946 and to examine the practicability and feasibility of individual programs. The statement that our defense program had to be reduced because our economy could not carry the load was proved unsound by this type of analysis. A full employment economy may be realized by a number of courses, such as high labor income, high capital expenditure, or a large governmental program. Which course should we adopt and what are the practical challenges and institutional changes necessary for the realization of each of these alternatives? Light on the analysis of these questions is shed by the projection technique.

We are abundantly provided with social goals and national values. In addition to the objectives spelt out by the Employment Act of 1946, we have inherited many from our recent history. The thirties left us with an inheritance of widespread sensitivity to our national well-being. Adequate national and allied defense is a continuing goal. In addition, groups are agitating for specific targets, such as better schools, medical facilities, roads, and other vital services. The trade-union movement is considering the possibility of a shorter work week. All these must be examined in the light of their effect on our economy. The model technique is particularly well suited to such investigations.

Many employing the forecasting technique have specific short-run and immediate business or local interests. They are concerned, not only with the performance of the American economy as a whole, the shortcomings of its

over-all attainments, and the need for general stabilization programs, but also with the impact on specific industries, areas and population groups. Unfortunately, the men making long-run projections of economic events have made few sallies upon the task of spelling out the specific effects of national economic growth upon the component industries or services. Studies on the effects on specific geographical regions have also been limited. As a result, the projection technique is unable to provide us as yet with the material for the full attainment of stabilization and growth.

We are currently witnessing the secular contraction of such large industries as coal, leather, and textiles, which have suffered in the midst of high national economic activity. The preoccupation with global figures has minimized specific concern for these groups. Even when the Council of Economic Advisers and the Joint Committee on the Economic Report were moved to interest themselves in these problems, they were distant and half-hearted. Yet, can one consider our stabilization authorities to have fully discharged their responsibilities unless they have similarly concerned themselves with the well-being of the individual sectors? They have committed the error of forecasting "by assumed momentum," which has proved false and misleading in connection with all three areas. We have not experienced any long-term recovery in any of them. Moreover, the decline of these industries has created serious economic problems for the textile areas of the eastern seacoast, the mining areas of the middle states, and the leather centers. Global studies must be joined with investigations of specific sore spots if stabilization is to be fully realized.

Howard R. Bowen: At the outset I should like to pay my respects to our speakers for introducing into the lexicon of economics two useful new terms. I refer to Mr. Bailey's "serendipity" and to Mr. Turner's "forecasting by assumed momentum." Serendipity, I take it, is a twentieth-century version of the "invisible hand," and "forecasting by assumed momentum" suggests the wisdom of Ecclesiastes: "The things that hath been, it is that which shall be; and that which is done is that which shall be done: and there is no new thing under the sun."

I am sure that our speakers are well aware that the positions they have taken are highly controversial. Perhaps they planned it that way. At least, each paper has aroused in me a lively spirit of dissent. First, let me take up Mr. Bailey's paper.

His general position, as I understand it, is that America should have a comprehensive national economic policy that is consistent with our basic values; that this policy should be formulated in the Executive Office of the President; and that this policy should be put into effect by means of a political program under the leadership of the President. With this much I am in agreement. But then, Mr. Bailey implies, the Council of Economic Advisers is to be a principal instrument by which all of this is to be done. Specifically, he implies that the Council should be not only a formulator of economic policy but also an active agent in seeking adoption of that policy by Congress. Here I find myself in disagreement. I think that the Council—at least if it is to consist

of economists—cannot, and should not, assume such responsibility. Professional economists are not suited to perform an essentially political task. If they were asked to perform it, they would be prevented from accomplishing the job for which they are equipped; namely, to give objective advice on the current state of the economy and on measures which might promote economic stabilization.

In my view, the Council should be a group of highly competent professional economists whose job it is to sift and place at the disposal of the President, in a comprehensible form, all the relevant accumulated knowledge, theoretical and empirical, of the entire economic profession. This is a tremendous task. If done well, it must be done by men who are primarily scholars rather than practical politicians. And if done well, it is a full-time job which leaves no time for political activity.

I do not mean to say that political work is unnecessary. Mr. Bailey has performed a great service in emphasizing that the job of getting economic policy adopted does not end with economic advice. Yet I doubt that the persons who are competent to give economic advice will also be effective as political operators. And I think that asking them to do both jobs will prevent them from doing either.

Obviously, as good economists, the members of the Council should not ignore political realities in formulating their advice. Also, I can agree with Mr. Bailey that the President should have the right to appoint and remove the members of the Council at his pleasure. He should have advisers with whom he can work and who are sympathetic toward his aims. But the Council should be primarily concerned with offering sound economic advice rather than with political expediency or political action.

Doubtless our government needs stronger political leadership; but it also needs more honest, disinterested advice on what is the right thing to do in order to achieve given ends. In the field of disinterested advice, professional economists have something to offer; in the field of political leadership, they have precious little to offer. I think economists should stick to their lasts.

Mr. Turner's position, as I understand it, is that stabilization policy requires forecasting; that within recent years we have learned to forecast with considerable reliability; and that we should confidently use our newly acquired skill in the formulation of stabilization policy.

I agree that considerable theoretical and statistical progress has been made in recent decades. I also agree that governmental economic policy has been fairly appropriate within recent years—though I suspect the explanation lies largely in serendipity and in forecasting by assumed momentum.

Regarding our ability to forecast the future reliably, I remain a skeptic. I have been profoundly impressed by the consistent differences of opinion among competent economists as we have headed into each minor recession since World War II. In each case, some have warned of inflation, some have expected a minor recession, some have envisioned a major depression, and some have looked for no change. In this guessing game, some have been right for the wrong reasons, some have been wrong for the right reasons, some have been wrong for the wrong reasons, and doubtless some have been right for

the right reasons. But have those who have been right for the right reasons been consistently right? And, if so, has this been a matter of chance or luck? Even if there are some conspicuously successful forecasters, how does a government identify them and see to it that they are in positions of influence?

Perhaps we need a statistical study of forecasters and their forecasts—with their annual batting averages published in the financial pages—in order to identify those persons who ought to be the official forecasters for stabilization policy.

It seems to me that we are not yet ready to speak with much assurance about future economic conditions. We still have not taken the really crucial test; namely, prediction of a major downturn. If and when such a catastrophe comes I have no doubt there will be those who will have foreseen it. But how are we to know which forecaster to listen to before the fact?

As you see, I am inclined to be a bit more pessimistic than Mr. Turner about our ability to forecast. On the other hand, I am more optimistic than he about the efficacy of built-in flexibility and the usefulness of compensatory action after the fact. Once we are in a depression or inflation, the fact can be recognized. At that time, there is some justification in forecasting by assumed momentum. At that time, moreover, political obstacles to fiscal policy and other stabilization measures are likely to be weaker than they were before the fact. Hence I conclude that in our present state of knowledge we had best continue to rely on compensatory policies rather than on policies based on specific forecasts which will at best have uncertain reliability.

RICHARD A. LESTER: Professor Turner asks that the Council of Economic Advisers face up to its statutory duty to forecast economic magnitudes. The fact is that for the past year members of the Council have made a number of predictions of one sort or another. For instance, last June at a press conference the chairman made a forecast with respect to capital investment, after the finger had been put on him at a presidential press conference. Professor Turner's plea, I take it, is for more systematic and well-documented forecasts and fewer economic forecasts via speeches and press conferences.

Professor Bailey warns that the Council members are participants in national policy making and should face up to the implications of their political positions. His admonition raises the question whether Council forecasts are not bound to contain political bias. At various times since 1946, Council members' predictions appear to have been designed to influence Congressional action or private spending, and it may well be that the function of policy formation and advocacy and the function of forecasting economic conditions should not be merged in a single agency.

At the meetings of this Association five years ago, Professor Erik Lindahl explained that in Sweden a group of economic experts in the government performs the technical task of calculating economic developments under alternative assumptions with respect to governmental policy and programs. The choice of the policy and programs is a separate function left to the political authorities. In the performance of its technical task of forecasting results under varying assumptions, the Economic Research Institute, headed

by Professor Erik Lundberg, has enjoyed a relatively independent position while housed in the Finance Department, and it apparently has avoided a political bias in favor of the government in connection with its forecasting activities.

In my opinion, serious consideration should be given to the establishment of some such semi-independent group of experts in the use of forecasting techniques in Washington. I have little faith in mechanistic methods of forecasting, and I am sure that the forecasts of any expert group would frequently be wrong, but a continuing agency would learn from experience and from the professional criticism of others. Such a group might be located, to use Professor Bailey's words, "in a dark corner of the Budget Bureau." Unlike the members of the Council of Economic Advisers, they should not change with each change of administration; continuing tenure would give them protection from—should I say "undue"—political influence and also the advantage of accumulating experience.

In looking back at the year 1954, I am surprised to find how close some private business forecasts came to predicting developments in, say, the level of the Federal Reserve index of industrial production or unemployment levels. Their January, 1954, forecasts contrasted with the Council's optimism for the immediate future. Perhaps there is a lesson to be learned in this difference of predictions.

Personally, I would place more stress on forecasts for the intermediate period than has been the practice in Washington. By intermediate I mean one to three years hence—specifically now that would be January, 1956, to January, 1959. Over the twelve months immediately following the Council's report, heavy reliance must be placed on built-in stabilizers and on discretionary action by the Executive Branch that requires no Congressional action that year, such as monetary policy. (Speaking of built-in stabilizers, the Council's recommendations last January with respect to state unemployment benefits were rather naïve and fruitless, and its discussion of minimum wages harked back almost to Nassau Senior. Lack of state or federal action to correct benefit levels under unemployment compensation that have been flattened down by increasingly low ceilings has given a great push to the guaranteed annual wage in such industries as automobiles.)

Each year the Congress should consider and take action to cover the forthcoming intermediate period. Admittedly, changes in the international picture make such planning and programing difficult and subject to alteration from time to time. It is, however, hazardous to neglect the intermediate years if the private groups who forecast so well for 1954 come close to being correct in their current forecasts of industrial production and employment for the years 1956 and 1957.

This country cannot afford to waste resources through idleness to the tune of 30 billion dollars of gross national product a year or three to five million unemployed. We need too badly such items as schools, roads, housing, and defense, not to mention the effects of unnecessary unemployment upon internal morale and our international prestige. Council Chairman Burns pointed out last October here in Detroit that "we are living in an age of

revolution" in which our economic system is in a world struggle for survival with communism and that we must, therefore, "be ready to take vigorous steps to help maintain a stable prosperity."

Forecasting and programing for the intermediate period should help to bring down to earth the repeated promises or threats of "bold steps," by focusing attention on a period longer than month to month or quarter to quarter. Of course, I am not unmindful of the fact that federal administrations have a four-year term and may find it difficult to plan beyond the next presidential election. Planning for the intermediate period is, however, one bold step that should be tried. It might very well help to increase the economic light and reduce the political heat.

CYCLICAL EXPERIENCE IN THE POSTWAR PERIOD

THEORETICAL SIGNIFICANCE OF THE 1949 RECESSION

By RENDIGS FELS
Vanderbilt University

There have been a number of good discussions published on the recession[1] of 1949, among others by one of the discussants at this session. The chief reason for bringing up the subject again is to use the episode to throw light on business cycle theory.

I shall be especially concerned with why some cyclical downswings seem to cumulate, resulting in severe depressions, whereas others come to an end quickly. Before I say anything more about cumulative contractions I had better define the term. By cumulative contraction I mean a business cycle downswing in which aggregate money demand for goods and services (or gross national product in current dollars), real consumption, and real private domestic investment all decline in at least two successive quarters (seasonally adjusted), the decline in the second quarter being greater than in the first. The idea of a cumulative contraction, which gathers momentum like a snowball rolling downhill, is familiar in the literature. But how do we distinguish cumulative contractions from any business cycle downswing? The mechanism of the cumulative contraction has two aspects: one monetary and one real. A reduction in output in current dollars ordinarily reduces disposable incomes (in current dollars), which reduces investment, and so on. Similarly, a reduction of real output reduces real investment, etc. It is possible for a contraction in money terms to occur without a contraction on the real side and vice versa, but in the actual world one kind of contraction cannot go on for long unless accompanied by the other. Consequently, the first step in ascertaining why a given business cycle downswing was mild is to find out whether both kinds of contraction occurred. For example, during the downswing which the National Bureau of Economic Research recorded as occurring in 1945, real consumption rose; therefore, there was no cumulative contraction. In cases where the downswing involves both the money and the real aspects of the mechanism, the next step is to inquire whether the downswing cumulated; i.e., gathered momentum. Consequently, the definition of cumulative contraction includes the proviso that the decline must ex-

[1] I define a recession as a business cycle downswing in which there is no cumulative contraction. I define a business cycle downswing as the period between a peak and the succeeding trough as determined by the National Bureau of Economic Research (see Arthur F. Burns and Wesley C. Mitchell, *Measuring Business Cycles* [1946], p. 78).

tend over two quarters and must be greater in the second than in the first.

The question why some but not all downswings result in severe depressions is important for theory. In some theories, such as that of Colin Clark and, to a lesser extent, John R. Hicks, the economy is inherently unstable, so that any downswing will lead to a severe depression unless some exogenous force intervenes. In those theories which utilize the distinction between major and minor cycles, on the other hand, downswings are mild if long-run investment opportunities are favorable and severe if long-run investment opportunities are unfavorable. Professor Hamberg and I both adhere to the latter view, and I am inquiring whether the 1949 experience proves us right.

The question why some downswings are severe, others mild, is not only interesting theoretically but also important practically. Formerly, when economists believed that full employment was the normal state of affairs, it was appropriate to focus on the upper turning point; that is, on the question why the economy should ever lapse from normal. We now know that there are a number of reasons why a downswing may get started. In the present economic and political climate of the United States, we can expect downswings to get started from time to time, as they have in the past. The problem of maintaining stability will be to keep the downswings minor. To do this we need to know a good deal more about what determines whether the downswing becomes a recession or a depression.

The downswing of 1949 is commonly referred to as an inventory recession. The reason for this is simple: the decline in inventory investment was actually greater than the decline in gross national product. I have no quarterly figures for GNP in real terms, but its decline was probably divided about evenly between output and prices. As usual, the fall in output was concentrated in manufacturing and the fall in prices in agriculture. Total civilian employment fell little more than 1 per cent between the fourth quarters of 1948 and 1949. Unemployment rose more than employment fell because the labor force was growing, but the decline of employment is a better measure of the force of a cyclical downswing. The contraction was evidently extraordinarily mild. It was also unusually short. The National Bureau of Economic Research dates the peak in November, 1948, and the trough in October, 1949, giving the contraction a duration of eleven months. Out of twenty-three contractions since 1857, only four have been shorter.

Few illustrations of the traditional theory of cyclical contraction can be found in the recession of 1949. It is true that in particular markets there was an "inventory-deflation spiral . . ., with reduced inventory investment driving prices down and falling prices inducing

smaller inventory investment" (Elmer C. Bratt, ***Business Cycles and Forecasting*** [4th ed.; Richard D. Irwin, Inc., 1953], page 346), and with the cuts in output decreasing the need for inventories and leading to still further cuts in inventory investment and output. It is true also that the decline in inventory investment was great enough to induce declines in a number of aggregate measures of business activity—not only GNP, employment, and industrial production, but also disposable income and investment in producers' durable equipment. These declines undoubtedly contributed in familiar ways to prolonging the downswing.

But one important aggregate was scarcely affected at all. Personal consumption expenditures in current dollars fell off in only one quarter, the first quarter of 1949. (Consumption of nondurables also fell in the second and third quarters, but this was more than offset by rises in durables and services.) If I had quarterly statistics of real consumption, they would probably show no decline in any quarter. Since a decline of real consumption is an integral part of a cumulative contraction, it is clear that no cumulative contraction (as I have defined the term) got under way. The fact that real consumption was maintained makes it easy to understand why the recession of 1949 did not degenerate into a depression. But this is only a first step in the analysis.

We must next inquire why consumption held up so well. To some extent the result can be credited to the combined effects of built-in flexibility, delayed effects of the tax reduction of the spring of 1948, and increased government expenditures; but if we take the statistics at face value (a hazardous procedure), we conclude that this was not the major factor. More important was the rise in the consumption function (see Table 1).[2] The reduction in disposable income was more than offset by a decrease in personal saving.

TABLE 1

GNP ET HOC GENUS OMNE

(Billions of current dollars, quarterly rates, not adjusted for seasonal variation)

	GNP	Personal Income	Disposable Income	Consumption	Saving
Fourth quarter, 1948	70.9	54.4	50.7	49.0	1.7
Fourth quarter, 1949	67.7	52.7	49.0	49.7	−0.7
Change	−3.2	−1.7	−1.7	+0.7	−2.4
Percentage change	−4.5%	−3.1%	−3.4%	+1.4%	

SOURCE: *Survey of Current Business.*

[2] Let us assume that normal marginal propensity to consume out of disposable income is one-half (the exact MPC assumed makes little difference to the comparisons that follow). With the decline in disposable income shown in Table 1, we would expect that consumption would have declined by 0.85 billion dollars. It actually rose 0.7 billions. This implies that

There are three explanations for the rise in the consumption function.[8] The best-substantiated is increased availability of automobiles (except for the fourth quarter, when model changing slowed output). This was one industry which had not caught up with demand in 1948. Automobile purchases in the next year increased by 2 billion dollars. To some extent, the fact that at the time of the recession an important industry was still expanding to meet demand deferred from the war must be regarded as an accident, but to a considerable extent this was a probable result of the forces which produced the inflationary expansion of 1946-48. Those forces made a bunching of the catching-up stages for different industries likely, but one could hardly have expected that all important industries would have reached that stage simultaneously. Here was an internal or endogenous mechanism which tended both to produce a business contraction and to ensure that the contraction would not make much headway.

The second explanation for the rise in the consumption function is well established, but its effects are difficult to measure. Consumer credit controls, which had been reimposed on September 20, 1948, were relaxed on March 7 and April 27, 1949, and finally allowed to lapse altogether on June 30. Statistics on consumer credit could readily be arranged to support the contention that the impact on consumption was considerable, possibly amounting to an annual rate of several billions of dollars. But the behavior of these statistics can be explained, at least in part, on other grounds such as increased availability of automobiles or the return to prewar seasonal patterns. Abolition of consumer credit controls was, of course, an external or exogenous factor.

A third explanation for the rise in the consumption function is plausible, but it seems impossible to get strong evidence for it. Slichter

---

consumption was 1.55 billion dollars higher in the fourth quarter of 1949 than it would have been had the consumption function not risen. If there had been no built-in flexibility and no change in tax rates, disposable income might have fallen by the full amount that GNP fell, namely, 3.2 billion dollars; i.e., 1.5 billions more than it actually fell. If we still assume that the marginal propensity to consume is one-half, consumption was 0.75 billion dollars higher in the fourth quarter of 1949 than it would have been without built-in flexibility and the tax cut. Therefore, under these assumptions the rise in the consumption function appears about twice as important as built-in flexibility plus tax cut. This no doubt puts an undue burden on the statistics, but there seems to be no question that the consumption function rose. In Table 1 I have taken advantage of the fact that the peak and trough both came in the fourth quarter of the year (ignoring the fact that the third quarter of 1949 was about as low as the fourth); this made it appropriate to use quarterly data not adjusted for seasonal variation, since the unadjusted figures presumably are more reliable. If I had followed the usual practice and used seasonally adjusted annual rates, the rise in the consumption function would have appeared nearly three times as important as built-in flexibility plus tax cuts; this would have been true irrespective of whether the third or the fourth quarter of 1949 was taken to be the trough.

[8] In addition, it should be mentioned that liquid assets were still fairly high and consumer debts fairly low; but these are reasons why the consumption function could rise, not why it did rise. The lag in adjusting to reduced incomes also deserves mention, although it could not explain why consumption in current dollars rose.

asserted that consumers in the fall of 1948 began postponing expenditures because they anticipated falling prices. Since consumers' stocks of goods were low and their bank deposits still large, he predicted that postponement of consumption would not last long. Since Slichter is a careful observer of contemporary business conditions, we can regard his assertion as a primary rather than a secondary source; and since he used it to make a successful prediction, we have a more convincing reason for believing his hypothesis than the mere weight of his authority. But there are nevertheless reasons for skepticism. For one thing, Slichter on a later occasion told a different story. For another, a single prediction may be right for the wrong reason. We therefore want confirming evidence. The "1949 Survey of Consumer Finances" provides some confirmation, though it is none too strong. If Slichter was right, here was another endogenous mechanism tending both to bring about a downturn once inflation died out and to limit the extent of the downswing.

The rise in the consumption function was not the only important reason why the recession was mild. As Gordon and Hamberg have stressed, autonomous investment was high; or to put the same matter in other words, long-run investment opportunities were favorable. Investment was still directed in large measure at shortages inherited from the war and therefore was not much affected by minor fluctuations in business activity. This is why investment in both construction and in producers' durable equipment fell so little. It should be noticed, however, that an endogenous factor was at work on the construction of houses. A decline in costs, as building materials fell in price and premium wages disappeared, bolstered construction because builders were able to shift into production for a lower priced market. In addition, an external factor may have affected private investment; namely, easier credit conditions following reduction in the reserve ratios required of member banks. But the main point undoubtedly was the autonomous character of private investment other than most inventory investment.

While we are on the subject of autonomous investment, we must discuss the most important external factor of the 1949 recession: the steady growth in government purchases of goods and services throughout 1947, 1948, and the first half of 1949. The increase in the first quarter of 1949 amounted to nearly three billion dollars and was caused primarily by higher military expenditures and increased foreign aid. Inasmuch as GNP declined only ten billions during the recession, seven billions of it in the first quarter of 1949 (annual rate), it can be seen that this was of great importance in keeping the contraction from cumulating. The level of government purchases reached in the first quarter was maintained throughout the year, a decline in the federal

component in the last half of the year being offset by rising state and local expenditures.

The foregoing analysis is still not adequate to explain why the recession was so mild. In the case of the downswing of 1920-21, there is evidence of strong autonomous private domestic investment and a rise in the consumption function; yet the earlier downswing quickly degenerated into a violent deflation. The chief reason for the difference appears to be speculation in inventories in 1919—a factor that was almost totally absent in the inflation of 1946-48. The history of depressions suggests that a speculative boom is a predisposing factor for a severe downswing. But businessmen were cautious during the upswing following World War II. The reason for their caution lay in their memories of the depression of the thirties, knowledge of what happened in 1919-21, and the highly publicized predictions (themselves partly the result of the depression of the thirties) that World War II would be followed by a depression.

Another difference between the downswings of 1921 and 1949 lay in the structure of the economy, which led to a different state of expectations. The inflation during and after World War I created the expectation that prices would have to fall; and whether that expectation was rational or not, in fact there were no serious obstacles to keep them from tumbling down. Expectations that prices would fall meant that when they began to fall they soon were falling precipitously. By the end of World War II, strong impediments to falling prices had grown up: powerful labor unions, price supports for agricultural products, and (it seems to me) an industrial shift towards maintaining prices in the face of falling demand. In addition, there were indirect assurances against falling prices: unemployment insurance and a government policy of actively combating depressions. These well-known developments gave businessmen and consumers the expectation that prices would not in any case fall very far, and the expectation in turn was a factor in keeping their decline moderate. There have been many theoretical contributions to the question of whether price inflexibility helps or hinders in maintaining full employment. The contrast between 1921 and 1949 suggests that in the latter case inflexibility helped avert what otherwise might have been a serious cyclical contraction.

Several years ago I published the statement that price flexibility in 1920-21 "appears to have shortened the depression by increasing aggregate spending." ("The Effects of Price and Wage Flexibility on Cyclical Contraction," *Quarterly Journal of Economics*, November, 1950, page 608.) There is no contradiction between this and the statement just made. On account of the speculative boom of 1919-20, there

would have been a cumulative contraction in any event. Price flexibility made the cyclical decline in prices greater but made the decline in output less; hence, price flexibility in that case was beneficial. The lack of price flexibility in 1948-49 helped keep a cumulative contraction from ever starting. The contraction of 1920-21 would have been worse if prices had not been flexible; the contraction of 1949 would have been worse if they had been flexible. This tends to confirm my earlier findings that price flexibility can help or hinder a cyclical contraction depending on the special circumstances of each case.

Such were the factors at work. The process whereby they brought the recession to an end can be described in brief compass. The small decline in output together with the rise in government spending and the maintenance of consumption enabled businesses to do in a short time what little liquidating of inventories they felt desirable. They soon were in a position of having to expand output in order to keep inventories from falling too far. When they did so, expansion got under way.

Now let me summarize the reasons for the mildness of the recession of 1949 preparatory to discussing what it does—and also what it does not—tell us about the nature of downswings in general. First, there were several endogenous or internal mechanisms at work: recent experience with severe depression, which served to prevent a speculative boom during the upswing; shortages inherited from the war,[4] with the high probability that some of them would not be satisfied by the time the recession began; the decline in the cost of building houses; and (possibly) the difficulty consumers had in continuing for long the postponement of expenditures which may have contributed to the upper turning point. Note that none of these endogenous forces can be depended on to operate in all future contractions. Second, there were two changes in the structure of the economy: the great increase in the importance of built-in flexibility and (to demonstrate how awkward the English language is) the increase in price inflexibility. The former can be depended on to help limit future downswings and the latter cannot. Third, there were several favorable external or exogenous forces: the increase in government purchases, the end of consumer credit controls, the cut in taxes, and the lowering of required reserve ratios of member banks. All these forces combined to prevent a cumulative contraction from getting under way. Which factors are classed as exogenous depends on the purpose at hand. The factors resulting in high, sustained, autonomous investment could appropriately be called exogenous; but I omit them. Since the question I am investigating is

[4] The war, itself, was exogenous, but the reaction of the economy to the shortages it created may properly be regarded as endogenous.

whether in a period of favorable private long-run investment opportunities a cumulative contraction can get under way and lead to heavy unemployment, it is irrelevant to inquire whether the reasons for the favorable opportunities are endogenous or exogenous.

I put the matter this way in order to stress that the recession of 1949 throws no light on the question I posed at the beginning: do we or do we not live in such an unstable economy that any downswing is potentially disastrous? External events, as well as some internal ones which cannot always be depended upon, intervened to prevent a cumulative downswing. If one had started, we just do not know what the result would have been, however tempting it may be to form a judgment and defend it as eternal truth. Colin Clark may or may not have been right when he wrote that "any fall . . . which has once reached a certain velocity will accelerate itself, and nothing is likely to stop the fall until investment has been reduced to the minimum replacement level. . . ." ("A System of Equations Explaining the United States Trade Cycle, 1921 to 1941," *Econometrica*, April, 1949, page 115.) I believe that Professor Hamberg went too far when he wrote "that an economy can withstand the impact of such inventory recessions as those experienced by the U. S. during the twenties and again in 1948-49, without tumbling into a major depression would appear as impressive testimony to the *stability* of the economy." (*Metroeconomica*, 1954, page 63—Hamberg's italics. This statement should be interpreted in conjunction with his discussion of 1948-49 in the *Economic Journal*, 1952, page 14, where he felt that the 1949 recession "bode [d] ill for the future.")

My conclusion disappoints me. Like Professor Hamberg, I want to use minor recessions such as 1949 to prove that our economy is not nearly as unstable as Hicks and Clark believe. But as long as this is an open question, economists ought to give different advice to the President and Congress when a business contraction starts than if we were sure that with investment opportunities favorable contractions come to a quick end by themselves. The temptation is great to conclude, consciously or unconsciously, that because the 1949 recession came to an end quickly future contractions will do the same.

I must, however, defend my view against an econometrician who tried to use this recession to throw doubt on Hicks's hypothesis of extreme instability. He started with a three-equation model consisting of the multiplier, the accelerator, and the national income identity, and fitted American statistics for 1947-50. He found a value for the accelerator far below what is required for explosive behavior and concluded that Hicks's hypothesis of an explosive accelerator appeared to be contradicted by the facts of this case. (Gene H. Fisher, "*A Simple*

Econometric Model for the United States, 1947-50," *Review of Economics and Statistics,* February, 1952, pages 46-48. He found an accelerator of 0.482, whereas to be explosive the value would have to be greater than 1.0.) But about two and a half of the four years he studied represented full employment. Under Hicks's theory, full employment may (and in this case undoubtedly did) reduce investment below the amount firms desired. For these years it is easier to reconcile a low value of the accelerator with Hicks's theory than it would be an explosive one.

It is not too difficult to reconcile Hicks's theory with the facts of 1948-49. His theory includes allowance for humps and slumps in autonomous investment. From the point of view of his theory, the 1946-50 cycle was a Bactrian camel. As you doubtless know, a Bactrian camel has two humps separated by a small slump.

In saying this, I do not mean to defend Hicks's theory. As Schumpeter once said, when we hang a man who deserves to be hanged, it is nevertheless important that we do not hang him for the wrong reason. (I must hasten to say that I do not believe Hicks's theory should be liquidated, much less that eminent economist's person; I am discussing only the application of his theory to one particular cycle.) The proper verdict to render on Hicks's theory in connection with 1948-49 is that it is not very helpful. To paraphrase Schumpeter again, autonomous investment is only a label for a blank space, and if we fill this blank space by some such thing as humps and slumps, we are filling a blank with another blank.

All of this is negative. Let me wind up with two positive suggestions for theory. Part of the rise in the consumption function was due to external events but part—perhaps the larger part—was not. This played a crucial role in heading off a cumulative process. It would be trite to say that the business cycle theory of the future must explain changes in the consumption function. The 1949 experience suggests that rather sudden shifts in the consumption function not only are significant for explaining business cycles but also may themselves have a cyclical origin.

Lastly, the speculative boom, which played a prominent part in some older theories but in recent theories is usually omitted, must be retained and explained. The presence of such a boom in 1919 and its absence in 1946-47 is one of the obvious differences between two cycles so similar in origin and so different in result. Had there been a speculative boom to collapse in 1948, it would have greatly changed subsequent events. The kind of explanation of the occurrence of speculative booms suggested here is old and familiar, running in terms of the recent experience with business cycles of business managers and investors.

BUSINESS FLUCTUATIONS IN THE UNITED STATES SINCE 1951: SELECTED DEVELOPMENTS

By Kenneth D. Roose
Oberlin College

Three fairly distinct economic movements have occurred in the American economy since 1951. First, the sharp rise in gross national product which followed the outbreak of the Korean war was interrupted early in 1951 by an inventory crisis although rising national security expenditures still maintained and gradually increased the gross national product during the period preceding the steel strike in mid-1952. Next, a resurgence in both private investment and consumption spending, beginning in the fall of 1952, carried gross national product and industrial production into new high ground in the spring of 1953. Finally, this peak level performance gave way when inventory and national security expenditures were reduced. The declines in industrial production and gross national product have apparently been checked, however, due largely to the expansion in new construction and consumption expenditures, an increased flow of government transfer payments, and reduced federal taxes.

Detailed examination of each of these periods of major change undoubtedly would be desirable and rewarding. However, time considerations severely limit the scope of the present analysis. As a consequence, the objectives of this paper are confined to three: to digest the basic economic developments from 1950 to 1954; to select, if possible, the crucial factors which contributed to the major economic swings of the period; and to advance some tentative observations concerning the near-term prospects in the economy.

Economic Developments, 1950-54

Gross National Product:

From an annual rate[1] of 264.9 billion dollars in the first quarter of 1950 (hereafter, 1950 I), gross national product, in current dollars, rose by 105 billions, or approximately 40 per cent, to a peak of 369.9 billions in 1953 II. In real terms, the increase was at least one-quarter. Almost 45 per cent of the rise, however, was concentrated in three quarterly periods: 18.5 billion dollars from 1950 II to III; 14.3 billions from 1950 IV to 1951 I; and 14.3 billions from 1952 III to IV. The total increase during the six quarters from 1951 I to 1952 III was only 24.9 billion dollars. Thus the behavior of the post-Korea gross national

[1] Data on the components of gross national product refer to annual rates unless otherwise stated.

product was characterized by sharp spurts interspersed by much slower periods of growth.

Following the peak in 1953 II, gross national product began to decline and at its low in 1954 III had fallen by 3.9 per cent, or about the same percentage as in the 1948-49 recession.

Personal Consumption Expenditures. Turning now to major components of the gross national product, the two waves in consumption expenditures following the outbreak of the Korean war are well known. From 189.1 billion dollars in 1950 II, personal consumption rose to 202.9 billions in III, and then declined to 198.8 billions in IV. Following their peak of 210.0 billions in 1951 I, they fell to 204.4 billions in the next quarter largely because of a 4.4 billion decline in expenditures on consumer durable goods. Consumption expenditures gradually rose thereafter to 218.2 billions in 1952 III. They then increased by almost 6 per cent to 231.2 billions in 1953 III as disposable income continued to grow and consumer credit rose sharply by 4.6 billions. More than one-half of this increase in consumption was from 1952 III to IV. Since declining to 229.7 billions in 1953 IV, consumer expenditures have risen moderately.

Gross Private Domestic Investment. The maximum increases in gross private domestic investment were 9.1 billion dollars from 1950 I to II and 9.2 billions from 1950 III to IV. Producer durable equipment and business inventories were responsible for two-thirds of the first rise while business inventories more than accounted for the second. From the peak of 62.6 billions in 1950 IV, gross private domestic investment fell by almost 25 per cent to 47.2 billions in 1952 II. The explanation is, of course, that investment in business inventories declined from an accumulation of 14.7 billions to minus .9 billions. The inventory problem was particularly acute for dealers in consumer durable goods. In the ensuing boom of 1952-53, private investment, led by business inventories, recovered to 55.9 billions in 1953 II and then fell by one-fifth to a low of 44.5 billions in 1954 I. All but 1.8 billions of this decline may be accounted for by the change in inventories which fell from 5.4 billions to minus 4.2 billions. An important offsetting factor has been construction which has reached new peaks in each quarter of 1954.

Federal Government Purchases of Goods and Services. Federal government purchases of goods and services rose steadily through 1953 II, with the exception of a billion dollar decline from 1952 II to III. At their peak of 62.2 billions in 1953 II, federal government expenditures for goods and services were three times as large as in 1950 II and III. National security items increased even more rapidly, rising from 17.2 billion dollars in the quarter preceding the Korean war to 54.3 bil-

lions in 1953 II, although their rate of increase began to decline early in 1952. Through 1954 III, federal government expenditures have declined by 14.3 billions to 47.9 billions, of which all but 2.2 billlons have been in national security expenditures.

State and Local Government Expenditures on Goods and Services. State and local government expenditures on goods and services have increased each quarter since 1950 II except for a decline of one-tenth of a billion dollars from 1951 II to III and one-half billion dollars from 1953 I to II.

Other Economic Series:

The other economic series which will be reviewed here are personal and disposable personal income, industrial production, prices, and interest rates.

Personal and Disposable Personal Income. Special interest attaches to personal income and particularly to disposable personal income because of their close relationship to the flow of expenditures. Personal incomes rose each quarter from 1949 III to 1953 III but declined moderately through 1954 I. Since then personal incomes have risen slightly.

Disposable personal income has shown even greater strength. With the single exception of 1952 I, disposable personal incomes have either remained unchanged or risen every quarter since 1949 III. Two factors bear primary responsibility for the increase in disposable personal income from 1953 III to 1954 III as gross national product was declining: the rise in government transfer payments from 12.6 to 14.7 billion dollars, and most important, the fall in personal tax and nontax payments from 36.3 to 32.9 billions.

Industrial Production. The Federal Reserve Board index of industrial production provides a relatively sensitive measurement of real production developments. From a low of 94 in the 1949 recession, total industrial production had recovered to a new post-World War II peak of 112 in June immediately preceding the Korean war. Subsequently, the index rose by 10 points, or 9 per cent, to 122 in December, 1950. It remained unchanged during the first five months of 1951 and then declined to 118 where it remained from August through October, 1951. The steel strike is reflected in the decline of industrial production from 121 in March, 1952, to 115 in July, 1952. It recovered rapidly thereafter, rising by 22 points, or almost one-fifth, to 137 in both May and July, 1953. Industrial production then fell by just over 10 per cent, to 123, in March and April, 1954, and was still at that level in August.

Behavior of Prices. Consideration must now be given to price changes. From a low of 100.4 in February, 1950, the consumer price

index rose by 10 per cent, to 110.3, in March, 1951. During the next two and a half years, consumers' prices increased by less than 5 per cent to their peak of 115.4 in October, 1953, and have receded less than 1 per cent since then.

The index of wholesale prices had reached 100.2 in June, 1950. Eight months later it had risen to 116.5. This proved to be the peak as wholesale prices, led by farm prices, fell to 109.4 in April, 1953, and remain at approximately this level today.

Interest Rates. Finally the movements of interest rates reflect the changing demand for and supply of funds and the dear and cheap money policies of the monetary authority. Yields on long-term US Treasury bonds provide a sensitive index of changing monetary policies. From a low of 2.19 per cent in December, 1949, yields rose gradually to 2.39 per cent a year later. Following the accord in March, 1951, yields rose to 2.65 per cent in June, 1951, and finally reached a peak of 2.74 per cent in January, 1952. They fell to 2.57 per cent in May, 1952, and rose gradually during the remainder of the year. The tighter money policy of early 1953 is clearly recorded in the rise of yields by over one-third of a per cent: from 2.75 per cent in December, 1952, to 3.09 per cent in May and June of 1953. Since that time yields have fallen again to a low of 2.47 per cent in April, 1954, and recently have firmed slightly.

Summary:

Summing up the general features of the period, the economy has been relatively stable as compared with pre-World War II cycles. The major fluctuations in gross national product have resulted primarily from alterations in rates of inventory, consumption, and national security expenditures. Producer durable equipment expenditures have been somewhat more stable than in many earlier fluctuations. Construction was also highly stable from the Korean war through 1952, ranging from 22.7 to 24.2 billion dollars. In 1953, however, it averaged 25.5 billions and has risen to a new peak in each quarter of 1954. Of unusual interest is the fact that from 1951 to the middle of 1953, whenever a major component of expenditure began to falter, some offsetting strength appeared. The relative weakness in consumption in 1951 led to an inventory crisis, particularly in durable consumer goods, which nevertheless failed to reduce the gross product because of the rising level of national security expenditures. Then as the rate of expansion in the latter tapered off, private spending revived partly to replenish stocks following the steel strike of 1952 but also facilitated by the expansion in consumer loans. Monetary policy was tightened early in 1953. Shortly thereafter, as consumption weakened again, national

security expenditures also began their decline and inventories started to accumulate. The heavy disinvestment in inventories and declines in national security expenditures were offset, but only in part, by increases in construction, consumption, and government transfer payments, and by tax reductions. As a consequence, the 1953-54 recession was mild, more comparable to the decline of 1927 than other pre-World War II recessions and approximately as severe as that of 1948-49, depending upon the statistical comparisons drawn.

Causal Factors

This is the empirical record. The areas of expansion and contraction have seldom been so clearly evident. As will appear below, however, despite the clarity of the statistical record, caution would still seem to be justified in interpreting the causal relationships, particularly in the latter part of the period.

From 1951 to the Steel Strike of Mid-1952. The inflation of the post-Korean boom was stopped in 1951 when the consumption function shifted downward. It is likewise probable that inventory expenditures declined also both because consumption weakened and because the cessation of the price rises ended the opportunity for further speculative inventory profits. A variety of factors weakened the forces of demand. For one thing, the extremely high level of expenditures had built up consumer stocks which appeared adequate for the time being once it became apparent that the flow of production of consumer goods would not be contracted excessively. Second, data from the Survey Research Center of the University of Michigan indicate that in its June, 1951, surveys more consumers thought it was a poor time to buy because of high prices than in subsequent surveys of 1951 and 1952. Third, merchants had overordered during the period of rapidly rising prices and hastened to restore more normal inventory-sales positions. In the fourth place, the harder money policies suggested that inflation was to be curbed. And, finally, when price ceilings were established consumers were encouraged to believe that the inflation was over.

In spite of the inventory crisis, gross national product continued to rise largely because of the further expansion in federal national security expenditures from 27.4 billions in 1951 I to 50.0 billions in 1952 II, an increase of 22.6 billions while gross national product went up 22.1 billions. Increases in personal consumption, net foreign investment, state and local government expenditures, and other federal expenditures approximately compensated for the drop in gross private domestic investment, leaving the increase in national security expenditures as the major factor in the rise in gross national product.

The Boom of 1952-53: From the Steel Strike Through the Second

Quarter of 1953. During the 1952-53 boom, gross national product rose by 28.5 billion dollars, or 8.3 per cent, from 1952 II to 1953 II. Personal consumption expenditures which rose by 14.1 billions and gross private domestic investment which rose by 8.7 billions (2.2 billions in construction and 6.3 billions in business inventories), together accounted for 80 per cent of the increase in gross national product. The dominant factors in this boom clearly were consumption and gross private investment. The expansion of 4.6 billions in consumer credit and the move to replenish depleted stocks supply the primary explanation for the strength in consumption and gross private investment.

The Recession of 1953-54: From Mid-1953 Through the Third Quarter of 1954. The turning point in 1953, as well as the behavior of the 1953-54 recession, is easily described in terms of the fluctuations in the components of gross national product but the causal relationships are more perplexing. By far the most important changes have been in the rates of government purchases and inventory investment. Government purchases declined by 11.0 billions. National security expenditures declined by 12.2 billions and other expenditures by 2.4 billions but were partially offset by a rise of 3.3 billions in state and local government expenditures. Gross private domestic investment fell by 10.6 billion, of which business inventories amounted to 10.2 billions. Construction and consumption expenditures have been the primary factors in checking the decline. Inventory changes, however, undoubtedly were the major private expenditure force in the turning point of 1953, but the reasons for their behavior seem less obvious.

The relatively high rate of inventory accumulation in 1953 II suggests that some part may have been unintentional. Prices declined slightly during 1952 IV and 1953 I. Therefore there seems to have been no price incentive to accumulate inventories. Some weight perhaps should be given to acceleration forces in explaining the inventory behavior since there was only a modest expansion in personal consumption between 1953 I and III. Personal savings as a percentage of disposable income fell from 8.5 per cent in 1952 III to 7.7 per cent in 1953 I but rose to 8.0 per cent in 1953 III. In the Hicks-Harrod view of turning points this could have been evidence of an approach to the production ceiling or the operation of a weak accelerator. As to the first view, production does not seem to have encountered a ceiling since symptoms of resource strain (inflation, production bottlenecks, etc.) were absent. As to the second, a weakness in consumption might reflect a redistribution of income. If, for example, a short-run shift of income in favor of profit receivers affects significantly the propensity to consume (and this is far from estabished), then the empirical developments of the

spring of 1953 may lend some support to the underconsumption version of the Hicks-Harrod model. Thus profits after taxes, although still considerably below the levels of the first three quarters of the Korean war, averaged 2 billion dollars more during the first three quarters of 1953 than they did from 1951 II through all of 1952.

The one other change in the spring of 1953 which conceivably might have upset business calculations was the establishment of the harder money policies. Interest rates firmed which undoubtedly had some effects on the demand for and supply of funds as well as on general business expectations. In the words of the Council of Economic Advisers in the January, 1954, *Economic Report of the President*: "The volume of new private flotations continued at a very high level but some difficulties were encountered at that time in marketing securities and placing mortgages." Apparently only consumer credit, which rose substantially prior to the initiation of more restrictive money policies, pointed toward the resumption of inflation. But the major inflationary boom itself had terminated almost two years before and prices in fact were declining moderately at the time the decision was made to tighten monetary conditions. In retrospect, therefore, these policies seem neither necessary nor wise.

Near-term Prospects

The present problem is at least threefold: first, to reduce the level of unemployment which is between 4 and 5 per cent of the labor force and to eliminate part-time work; second, to provide 500,000 to 700,000 new jobs annually to take care of the growing labor force; and, third, to secure the normal increase in productivity of between 2 and 3 per cent per year which requires an annual growth in the national product of between 7 and 10 billion dollars.

Although the immediate prospects for achieving all three of these objectives are none too bright, an upturn in general business seems to be under way and is likely to continue for several months at least. National security expenditures have leveled out but other federal government expenditures are planned to increase moderately during the current fiscal year and state and local government expenditures will continue their slow climb. Consumption has been well maintained and is increasing although there is no reason to anticipate a sharp shift upward in the consumption function. In this connection, it is worth noting that at present levels of disposable income personal consumption would change by only 4.5 billion dollars, before any multiplier effects, if personal savings were to fluctuate between their high and low ratio to disposable income since 1951 I. Some help may be expected

from gross private domestic investment if construction gains offset declines in producer durable equipment expenditures and if disinvestment in inventories gives way to inventory accumulation.

This very cursory examination of the prospects for expenditure indicates that a moderate recovery may be forecast although the forces for a substantial upturn are not yet in sight. It should be observed, however, that in many earlier fluctuations unexpected forces have made important contributions to revival and expansion. Nevertheless, the fact remains that unless there is a significant improvement in one of the major components of national expenditures, the gains from increased productivity are likely to be lost in increased unemployment or perhaps disguised unemployment (shorter hours, reduced labor forces, etc.). The mildness of the slump in production during the 1953-54 recession may suggest that the short-term or cyclical problem is giving way to long-run considerations which are to raise the level of product and the general standard of living. Whether this proves true or not, it would still seem desirable to give more attention to the problem of the "long haul"—to analysis of the secular factors which can undergird a progressive economy.

DISCUSSION

JOHN LINTNER: The two papers by Professors Roose and Fels provide a good review of the 1949 recession and subsequent cyclical experience in terms of the observed changes in broad aggregates and indexes. The analysis of these developments in both papers offers much that will be useful in subsequent work. In keeping with the chairman's invitation to serve as a general discussant for the session, I shall address myself briefly to two broad points raised by these papers, leaving detailed comment to the other discussants. While neither of the points is new, both seem sufficiently important to justify comment in the present session.

My first point has to do with the adequacy of analysis in terms of such comprehensive but often inherently heterogeneous aggregates as those used by the present authors and by economists generally in most of their work on business cycles. (The most significant exception to reliance on such aggregates in the present papers is Fels's distinction between the behavior of automobiles and other consumer durables in the 1949 recession.) It is certainly true that most of the major advances in this field over the last generation can be directly attributed to the development of national income accounting and related statements of money flows, on the one hand, and to the formulation and (usually mathematical) exploration of the properties and implications of theoretical methods specifically oriented to such aggregates, on the other. No one would want to question the great significance of the advances which have been made along both these lines, nor even the current usefulness of such efforts and analysis. But serious questions do need to be raised concerning the adequacy of analyses which deal only with comprehensive aggregates to meet the demands increasingly being put upon economists in this area. The development of sounder judgments on prospective business conditions leading to more responsible policy decisions as well as the necessary further scientific progress through tests of existing theories and elaboration of still better theories are going to depend heavily upon much more attention to the detailed components and shifts in the structural composition of important aggregates than has usually been given. The fact that data on many of the important components of our global aggregates are not readily available or that they are not precise enough to support firm conclusions does not lessen the need for more analysis at this level. These considerations simply put an added premium on efforts to develop and refine the empirical data required for such investigations.

Time permits no more than a single illustration. For this purpose, consider the important issue of the existence and extent of non-random shifts in the consumption function over the cycle. Both authors treat the consumption function as a behavioral equation (as it should be), but in keeping with the usual analysis of such issues, both then go on to infer the presence or absence of shifts with behavioral significance from comparative movements in consumption and disposable personal income in spite of the fact that this income aggregate encompasses unincorporated businesses, farms, and other nonpersonal economic units. For brevity, I shall confine my specific comments to Fels's

finding that an upward shift in the consumption function was more important in maintaining a relatively high bottom to the 1949 recession than the combined effects of built-in flexibility, the delayed impact of prior tax reductions, and current increases in government expenditures. His argument runs that since disposable income fell between the fourth quarters of 1948 and 1949 by 1.7 billion dollars, consumption would have fallen a substantial fraction of this amount if the function had not shifted. Since consumption actually rose by 0.7 billions, the function must have shifted upward by 1.6 billions or more. If Fels had assumed a marginal propensity to consume, say, 0.8, the indicated upward shift in the consumption function would have been 2.05 billion dollars. (Differences in the assumed value for the marginal propensity to consume do not significantly affect the estimates given below because of the very small value estimated for the change in disposable income that would be expected to have a net effect upon consumption expenditures.) But between the two fourth quarters, there was a reduction of 1.9 billion dollars in the rate of inventory accumulation in unincorporated businesses and on farms. *Ceteris paribus,* this involved an equal reduction of like amount in both personal income and personal savings. (I am here ignoring the changes in bank debt usually associated with inventory changes, since in this period reduced inventory was accompanied by increased rather than by reduced indebtedness. Data are from Irwin Friend's *Individuals' Savings,* published in 1954 by John Wiley & Sons, especially pages 46 and 47.) With tax payments and accruals virtually constant as they were, such changes have a multiplier of one with no repercussion effects via induced changes in consumption. Exclusive of income simultaneously created by and automatically reinvested in increased noncorporate inventories, disposable income on the basis of the available figures rose by 0.2 billion dollars; at the same time, personal savings other than those "automatically" invested in such inventory increases declined by only 0.5 billions. The resulting shift indicated in the consumption function is less than ¾ billion dollars, which is less than the probable effect of built-in flexibility alone and consequently substantially less than the combined effects of such flexibility, changed tax rates, and increased government spending. Indeed, since the indicated size of the shift is considerably smaller than the margins of error in the data, it is not even clear that the consumption function actually shifted at all. A much more detailed analysis than is appropriate in these remarks—and based on much better and fuller data than are presently at hand—would be required to settle the issue.

In order to avoid unwarranted implications, let me add that, like the authors, I am inclined to believe that there are significant non-random (as well as random) shifts in the consumption function during cyclical fluctuations, but what they are and why they are is still vague pending much more extensive and detailed investigation. At this time, my concern is simply to illustrate the proposition that we must use more detailed breakdowns than those provided in the present national income aggregates to test our hypotheses and develop our insight. A balance must of course be struck at some point. Perfect homogeneity of components is unattainable. Gains in homogeneity and relevance to the actual data, motivations, and processes of de-

cision making must always be weighed against costs in terms of complexity of models, less accuracy in data, and so on. (Budget studies and other cross-sectional analysis can go far toward meeting many of these problems.) But the economic balance between aggregation and disaggregation for cycle analysis surely lies in the direction of more detailed study of the components making up our aggregates than has generally been the practice. This proposition seems clear enough in terms of the economists' traditional effort to push toward the point of equality between incremental gains and losses; it can perhaps be made even more forcefully in terms of seeking minimax solutions in the allocation of our efforts.

My second general observation suggested by the present papers concerns what we may reasonably expect in the foreseeable future in the way of "a satisfactory theory" of business cycles. Useful historical or empirical work necessarily involves major elements of testing hypotheses incorporated in existing or new theories. The implications of the indicated modifications of hypotheses must be explored theoretically and new formulations developed for subsequent testing. This combination of theoretical and empirical work has produced the very real progress toward more satisfactory theories of the cycle which has been achieved over the last quarter century, and continued scientific work along these lines will undoubtedly produce much more satisfactory theories than we now have. Such studies at the micro as well as the sub-aggregate and aggregative levels should throw valuable light on the determinants of different types of saving and consumption and both the real and monetary factors which most importantly influence investment expenditure. Important distinctions and valuable new insights will unquestionably be gained as attention is turned to the separate components of all that is now lumped together vaguely as "autonomous" investment and as allowance is made for the distinctive impact on the rest of the structure of equal absolute or relative shifts in such distinctive types of investment. These developments should be particularly important in relation to the central question of the relation between longer term growth and cyclical fluctuations.

It would be a mistake, however, to hold out the promise that these prospective developments will do any more than narrow the range of differences in judgment and advice respecting policy which economists offer policy-makers. Any economic theory is necessarily partial and subjunctive in character. Even if we had an adequate formulated and verified theory of the operation of what are generally regarded as endogenous factors in the cycle, there would continue to be major differences in judgment regarding the probable future impact of exogenous factors. Since behavioral equations adequate to explain changes in endogenous variables necessarily include exogenous variables (or parameters functionally related to the level or rate of change of such variables), the reaction mechanism of the system will depend on values assigned or assumed for these other factors in each case. At still a different level there would continue to be differences in judgments regarding proper policy because of differences in the relative importance attached to alternative policy goals.

In sum, forseeable developments in the analysis of cycles will undoubtedly improve our understanding of the processes involved. They will consequently

give us a better basis for the judgments underlying our recommendations in particular cases, but significant differences and uncertainties in judgment will undoubtedly remain. Policy recommendations will consequently have to continue to be adapted to such uncertainty, and studies of how this adaption can be made more effective must press forward along with the study of the cyclical process itself.

DANIEL HAMBERG: I should like to devote my discussion to two aspects of Professor Fels's interesting paper. One is the tasks of business cycle theory; the other is the emphasis given the caution of businessmen with respect to inventory accumulation in the postwar period in Fels's explanation of the limited magnitude of the 1949 recession. In the latter connection I shall suggest a hypothesis for expecting inventory recessions per se generally to be limited in magnitude and perhaps become even more so in the future.

A major task of business cycle theory is to explain why prolonged periods of growth are sometimes interrupted only by mild inventory recessions—recessions that do not degenerate into major depressions—while at other times the lapses from growth take the form of major debacles of the magnitude of those of 1872, 1892, or 1929. Closely connected with this task is the correlative one of explaining why some cyclical upturns rapidly cumulate into extended periods of full employment growth (with only minor interruptions), while others, like those of 1892 or 1933, are markedly lacking in vigor and buoyancy, either barely reaching or actually falling short of full employment before the upper turning point.

Many business cycle analysts endeavor to explain these differences by emphasizing a constellation of fortuitous circumstances that may be associated with the individual upper or lower turning points. Among this group may be numbered such writers as Professor Slichter and generally those that have written under the auspices of the NBER.

Along with many other cycle theorists, however, I would disagree with this type of explanation. In the main this disagreement probably stems from an innate desire to look for a more systematic explanation—to look for factors that all inventory recessions, for example, appear to have in common. The same kind of search is associated with the examination of the major downswings as well as with the effort to explain the broad differences in upswings mentioned earlier.

Analysis of the inventory recessions of the past has thus led many cycle theorists, those whom Fels describes as placing the emphasis on "long-run investment opportunities," to the observation that the common denominator of all of these recessions is a surging rate of innovational investment and, almost without exception, a similar behavior on the part of residential construction. (This fact leads me to discount somewhat the significance of the apparent upward shift in the consumption function in 1949 as a major explanation of the mildness of that recession. The recessions of the twenties were equally mild, without any corresponding behavior on the part of consumption.) At the same time, those downturns that cumulate into major depressions appear to coincide with the (temporary) drying up of these outlets

for fixed investment. Invariably, too, the aforementioned differential behavior in upswings following major depressions seems to depend on the presence or absence of major innovations and high volumes of residential construction.

In the realm of systematic explanations of business cycles, also, are the endogenous or self-generating theories, particularly those that employ a multiplier-accelerator mechanism or some variation of it, like the models of Hicks, Goodwin, Clark, Kaldor, and Kalecki. These and virtually all other self-generating theories, however, suffer from the fundamental defect of imputing to capitalism more instability than actually exists, and there is enough already. For in their basic features, as Professor Fels has suggested, they imply that all movements in national income, upwards and downwards, tend to be explosive or antidamped. Except through appendaged obiter dicta that change them in basic ways, these models are incapable of dealing either with inventory recessions or with those periods of temporary stagnation sometimes described as weak cycles.

The lone exception to this statement is the remarkable model of Professor Frisch, developed some twenty years ago. Modified to allow the erratic shocks of autonomous investment to vary in frequency according to the magnitude of the shock (the larger shocks occurring less frequently than the smaller ones), the Frischian model meets the long-standing objection that it lacks the characteristic of systematic fluctuation that seems to have marked the business cycles of the past (cf. M. Kalecki, *Theory of Economic Dynamics*, Chapter 13). The principal posers of this objection have been among those advocating the assumption of antidamped cycles. With the objection disposed of, there is no longer any reason to continue to assume a priori that such cyclical behavior constitutes the underlying tendency of capitalism. When the aforementioned modification of the Frischian model is made, fairly regular cycles are produced by models possessing heavy damping coefficients as well as those with moderately damping coefficients. From the viewpoint of cycle theory, this is an important point, for it is only a model with heavy damping coefficients and kept alive by the irregular behavior of autonomous investment that is able to cope in self-contained fashion with the task of explaining not merely the systematic aspects but also the *differential* behavior of business cycles.

The necessity of a concept of fluctuating autonomous investment, i.e., investment based on other than income change, is apparent. The resistance to such a notion, even conceptually, is strange, since it is clear that certain categories of investment can in no way be related to the sale of goods already being produced. Though such investment can be influenced in its timing by income level, the important thing is that this relation is unsystematic. Not only may autonomous investment not fall during certain downswing phases, thereby limiting the latter to inventory fluctuations, but it may not rise during some periods of cyclical upswing, giving rise to periods of temporary stagnation. At the same time, it may also fall in the face of rising income, leading inevitably (in the absence of appropriate government policy) to the major downswings like those experienced in the past.

If pressed for a generalized explanation of the origins of inventory re-

cessions, I would point to the many possibilities of industry or sector maladjustments that may arise in a free market economy using roundabout methods of production. Over- or underestimation of demand in certain sectors, or, perhaps more important, unforseen shifts in the composition of aggregate demand—all in the face of a certain amount of immobility of resources—these are the most likely candidates in looking for explanations of upper turning points. But when the aggregate economy has strength and resiliency imparted to it by the surging streams of innovational and residential investment, during those irregular periods of growth, it shows itself quite capable of absorbing these sectoral maladjustments within the limits of inventory recessions. When these autonomous investment outlets are more or less absent, the same maladjustments find the bottom dropping out of the private stream of expenditures.

With these remarks as background, I should now like to call your attention to factors that may be expected to make inventory recessions generally mild (so long as long-run investment opportunities are favorable). Professor Fels expresses a feeling of inadequacy with the emphasis given the apparent upward shift in the consumption function and the strength of autonomous investment in his explanation of the mildness of the 1949 recession. To bolster his argument he feels called upon to cite the comparative absence of inventory speculation in the period preceding the recession. His suggested reasons for this state of affairs are that businessmen remembered what happened in 1919-21 when they engaged in inventory speculation, that memories of the depressed thirties added to their caution, and that this caution was furthered by the predictions of postwar depression.

It is difficult to believe that the current crop of decision-makers would be significantly influenced by what happened in an inventory cycle some quarter of a century earlier. Most of them were either nonexistent as businessmen or were probably in very low echelon positions, and it is very likely that their knowledge of what went on at that time is quite dim. I find this suggestion just too implausible.

More seriously may we take the suggestions about the effects of the memories of the depressed thirties and of the predictions of early postwar depression. There is no time to discuss analytically the general merits of these suggestions. On the empirical side, however, the events of the postwar period appear to contradict such notions. In brief, Fels is suggesting that postwar business sales expectations were inelastic. Under these circumstances one should expect to find business investment concentrated in just that area where the turnover is rapid and where therefore funds would not be irretrievably tied up in the event of imminent depression. In turn, this implies that inventory investment should have played a dominant role in total investment, while fixed investment should have played a correspondingly minor role. This is just what occurred in the years 1919-20; but of course, exactly the opposite happened in the post-World War II period. For one observer at least, the latter fact—the fact that so much was spent on fixed capital especially—provides ample testimony that business expectations were quite elastic in the recent postwar period.

To what then can we trace the absence of inventory speculation in the postwar period? In answer, I would reply that this kind of behavior should be regarded as entirely normal, that it is the periods of inventory speculation that are exceptional and require special treatment. On the whole, economists have been prone to exaggerate greatly business propensities to speculate in inventories on future price movements. In contrast to this picture is the real one, which shows that businessmen generally have a strong aversion for inventory speculation. Most think in terms of making profits out of their essential business operations; i.e., their production and sales operations, the appeal of their (differentiated) products. Rather than engage in activity whose sole feature is speculation, businessmen generally prefer to concentrate their energies on affairs over which they believe they have more control, where their training and talents give them a greater feeling of security. In a basic sense, an element of speculation inheres in all roundabout methods of production or purchasing in anticipation of demand. But this is unavoidable. It does not mean that businessmen favor it. In fact, much business activity is best understood if viewed as efforts to reduce risk and uncertainty. By the same token, the implication is that businessmen will not go out of their way in quest of unnecessary risk and speculation, such as is involved in price speculation in inventories.

Good, conservative business practice frowns on pure speculative profits. Proper inventory practice "is said to consist in maintaining such a relation between output or shipments (or sales) as is required to support the normal functions of production and selling." (Abramovitz, *Inventories and Business Cycles,* page 184.) The reasons why businessmen look askance upon inventory speculation are manifold. For one thing, guesses as to future price behavior may prove wrong as well as right; the possibility of inventory losses may therefore stand on an equal footing with that of inventory profits. Inventories tie up cash balances; other things equal, they make a business firm less liquid and leave it more exposed to disaster through illiquidity. The threat of bankruptcy because of illiquidity is something to which every businessman is keenly sensitive. Moreover, if he has to borrow from a bank to finance inventory speculation, his banker will be suspicious and most likely uncooperative. It will be made clear to him that he is no longer regarded as a solid, conservative businessman, that his credit is no longer as good as it formerly was.

In addition, the businessman—manufacturer, wholesaler, or retailer—who engages in speculative inventory purchases must face the added costs incident to storage, handling, obsolescence, depreciation, interest, insurance, and possibly property taxes. His storage space may be absolutely limited.

These remarks are not intended to imply that business firms never speculate to any degree in inventories. Thus when sales are rapidly advancing, individual business firms may often be found to be building up inventories somewhat faster than the growing sales. Even this action, however, is likely to be motivated principally by the desire to ensure maintenance of the share of future markets; that is, protect against slow deliveries, poor selection, etc. At times, also, salesmen may tip off buyers of an impending price increase,

and the latter may respond by stocking up heavily in advance. Again, however, this may not reflect pure inventory speculation so much as it represents an effort to protect the business firm's competitive position. Pressures in this direction are likely to be especially strong if one's competitors are known to possess large stocks purchased at the lower prices.

Granting these possibilities as to "speculation," as a rule such cases do not represent the commonality of experience, such as might be expected to generate cyclical movements in GNP. The only important exception to this rule arises in connection with sudden developments like the Korean war or the wave of speculative buying following World Wars I and II. Under such circumstances, past experience, rightly or wrongly, may lead businessmen into efforts aimed at large-scale inventory build-up in anticipation of later shortages or high sales levels. However, the motivating force in this situation, too, is likely to be less a desire to cash in on high future prices than a fear of just getting stuck with little or nothing to sell. In any event, these circumstances may be assumed exceptional enough to warrant separate explanation. The behavior of businessmen under these conditions is not characteristic of their usual peacetime practice and will tend to give rise to mistaken results if applied in an analysis of inventory fluctuations of the kind experienced in the distant past, 1948-49, or even 1953-54.

The implications of the foregoing remarks should be clear. They suggest that "normally" inventory cycles as such may be expected to be mild. Violent inventory fluctuations like that of 1919-21 must be explained in terms of special circumstances. Thus Professor Fels's emphasis on the caution of businessmen as regards inventory investment during the postwar period must be taken to be misleading, for such caution is the usual earmark of business attitudes toward this category of investment. Instead, he might well rest his case on the stabilizing role of autonomous investment behavior, aided and abetted by the fortuitous upward shift in the consumption function.

In closing, I should like to offer a hypothesis that not only may inventory recessions per se normally be expected to be mild in character, for the reasons elaborated above, but that there is some reason to expect a secular growth in mildness; i.e., diminution in both amplitude and duration. Examination of the data on inventory-sales ratios leaves one with the strong impression of a secular decline in these ratios; the only important exception to this trend seems to be in certain areas of durable manufactures. A priori, there are many good reasons that can be offered in explanation of this apparent trend. One is the movement toward industrial integration—a movement that recently seems to have developed renewed impetus. Vertical integration may be expected to reduce inventory-sales or output ratios by lessening the instability of supply taking the form of variations in delivery rates and prices of materials. Horizontal integration may also have the same effect by reducing the amount of inventories held as safety allowances against unforeseen variations in supply and demand, "for deficiencies in one plant may be compensated for by excesses in other plants" (Whitin, *Theory of Inventory Management*, page 149).

Perhaps even more important in explaining the downward trend in inventory

ratios are the widespread improvements in transportation, communications, production methods, accounting control techniques such as IBM methods, and standardization of product. There is every reason to expect continued improvements in technology, etc., with their resulting tendencies to reduce inventory-output or sales ratios.

Now the general consensus on the role of inventories in business cycles is that on the whole they are destabilizing, even when cognizance is taken of their stabilizing function as shock absorbers. Much of the destabilizing effects of inventory investment may be associated with the inventory accelerator; i.e., the desired ratio of stocks to output or sales. Few, at any rate, are likely to quarrel with the statement that, *ceteris paribus*, the duration and amplitude of inventory cycles are likely to vary directly with the value of the inventory accelerator. Whence it follows that the secular decline in this accelerator may be expected to have a general damping tendency on inventory cycles.

But this is not all. Most analyses of the role of the inventory accelerator have been based on the assumption of a linear accelerator. Recently, however, modern inventory control methods have shown that optimal inventory policy dictates that inventories should vary less than proportionately with changes in sales (see Whitin, *op. cit.*, Chapter 3). Introduction of such a variable accelerator also has a decisive damping effect on inventory fluctuations (see *ibid.*, pages 121-124). Contrary to the opinions of most economists on this matter, there is some evidence that many businessmen at present plan their inventories to behave in this manner, though for a variety of reasons. In part, this may account for the mildness of some of the recent inventory recessions. Beyond this, however, as modern inventory control methods attain wider use and more and more businessmen see the wisdom of varying inventories less than proportionately with sales, there is a further basis for expecting future damping in inventory cycles.

Finally, I should like to draw attention to what seems to be a trend away from FIFO in favor of LIFO accounting systems. To the extent that there exist any propensities to speculate in inventories, this switch should tend to reduce them. For the profits on inventory that arise during periods of advancing prices are wiped out under LIFO bookkeeping methods.

One final word in self-defense. My statement, quoted by Professor Fels, to the effect that the inventory recessions of the past testify to the stability of capitalism should not be misconstrued. It was made with those models in mind that indicate explosive behavior following all turning points. From the point of view of policy recommendations, I quite agree with Professor Fels that there is no basis for inferring from the 1949 and other similar experiences that major downswings are a thing of the past, as there is evidently some tendency to do currently. This view, however, is perfectly consistent with the notion that not all upper turning points may be expected to degenerate into major downswings—so long as there continues to exist an important category of investment that is independent of income change. The link between these seemingly opposing views lies in the fact that we do not as yet have tools that enable us to know in advance when there is a sufficient volume of "long-run

investment" outlets to limit downswings to the magnitude of inventory recessions and when there is not. But this is a problem of forecasting, not theory. Nonetheless, as long as our forecasting techniques remain weak, I for one would recommend policy based on the cautious assumption that any upper turning point poses a threat of major depression.

EARL C. HALD: Professor Roose has given us a concise summary of business cycle developments in the United States over the past several years. Much of of his analysis and most of his conclusions would seem to require nothing from me but expressions of hearty approval. I particularly welcome the note of caution he employs in surveying the future—a note that needs to be sounded for the benefit of those who, dazzled by the gyrations of the stock market and delighted to find that the production of steel at 75 per cent of capacity is still a highly profitable operation, are saying that the 1954 recession has been only a slight hesitation in the onward march of prosperity and high employment. Apart from, and yet affecting, the outlook for the future, certain aspects of the 1952-53 boom and of the 1953-54 slump may be worthy of more comment and analysis than could be brought to bear by Professor Roose within the limitations of his paper.

Pointing out that consumption rose by 14.1 billion dollars (at annual rates) from the second quarter of 1952 to the second quarter of 1953, and that investment rose by 8.7 billion dollars during the same period, Professor Roose says: "The dominant factors in this boom clearly were consumption and gross private investment." Although the importance of the increases mentioned was obviously great, one may question the omission of a reference to government spending for goods and services, which rose by 8.5 billion dollars during the same period, or almost as much as investment gained. It seems clear that this increase in the government portion of the spending stream substantially affected the character of the boom, just as the fall in government spending during 1954-55 has been of significant, if not dominant, importance during this latter period. As for the rise in consumption in 1952-53, it should be pointed out that consumption as a percentage of disposable income actually fell during the 1952-53 boom, personal saving having risen from 7.3 per cent of disposable income in the second quarter of 1952 to 7.8 per cent in the same quarter of 1953. (It is interesting to note that the proportion of disposable personal income saved continued to rise throughout the third and fourth quarters of 1953 but has fallen rather sharply in the second and third quarters of this year, coincident with the leveling out of the slump.) On the basis of these data it would perhaps be more accurate to say that the character of the 1952-53 boom was shaped primarily by government spending and private investment and much less by consumption spending.

Professor Roose comments only in passing on what is to me one of the most interesting aspects of the 1953 downturn; namely, the part played by monetary policy, as reinforced by Treasury interest rate policy, early in 1953. The focus on monetary policy has been sharpened by statements made lately, on the one hand, by its defenders to the effect that the easing of credit conditions beginning in May, 1953, saved the economy from a more severe depres-

sion and, on the other hand, by its critics that the tight money policy of early 1953 caused all of our troubles, and therefore the monetary authorities should not now be reminding us of how fortunate we are that conditions did not become worse than they actually proved to be! On this subject, Professor Roose merely points out that, judged by the behavior of the price level, the major inflationary boom had terminated well before 1953 and that therefore the decision to permit credit tightness to continue and even to be accentuated early in that year seems "neither necessary nor wise."

Needless to say, the part played by monetary policy in shaping the course of events during any period is extremely difficult to assess. This is partly because the real impact of monetary policy may not be manifest in the behavior of interest rates, which can be observed, but may appear in that obscure and indefinable area we call the availability of credit. Moreover, we must think of monetary policy also in terms of its indirect influence on the expectations of both entrepeneurs and consumers—not to mention the expectations of bankers, which may be of equal importance. In assessing the reasonableness of monetary policy early in 1953, however, we may begin by pointing out that, although the rise in wholesale prices had reached a peak early in 1951 and there had been some decline through June of 1952, the picture during the remainder of 1952 and early 1953 was by no means a clear one, and both wholesale and retail prices showed stability and at times even a rising tendency during the first three months of 1953. In view of all the indicators at hand, perhaps the conclusion of the monetary authorities that the inflation potential was still present is understandable.

There is little evidence that Federal Reserve authorities actively desired to tighten money rates in the spring of 1953. It is true that the rediscount rate was moved up from 1¾ per cent to 2 per cent in January, but this may be explained in part by the fact that the lower rate had been in effect for more than two years during a period of rising market rates and that the Federal Reserve authorities simply felt it was getting too far out of line with market rates. Moreover, the announcement of the rate increase just before the accession of the new administration to power implies perhaps more than anything a desire to dissociate this change, which had been contemplated for some time, from the policies of that new administration, which had already been revealed to be in favor of higher money market rates. After January, Federal Reserve ownership of government securities remained virtually unchanged until May, when an active program of open market purchases was inaugurated. Reserve requirements were permitted to remain at the levels which had prevailed for two years. It would appear proper to describe the policy followed by the monetary authorities throughout February, March, and April of 1953 as one of watchful waiting, after which a decision was taken to embark upon a policy of definitely easing credit. Meanwhile, the increasingly strong demand for credit continued to push market interest rates upward, the peak as measured by the prevailing rate on long-term government securities being reached in the first week of June.

How large a part was played by Treasury policy in the rise of interest rates between January and June is of course impossible to say. It is only fair to

point out, however, that there was a great deal of talk, both publicly and privately, to the effect that Treasury officials of the new administration were determined to convert at least part of the maturing debt into securities of much longer term, and that they were aware that this would require an interest rate structure higher than had heretofore prevailed. It is my belief that this announced policy had a good deal to do with the reaction of the money market, and that to the extent that the interest rate pattern of this period was due to government policy action, the blame or credit, as the case may be, must attach to the actions of the Terasury as much or more than to the actions of the monetary authorities. One might even go so far as to suggest that the tendency of the Treasury to "run with the ball," so to speak, resulted in such a sharp rise in interest rates that the monetary authorities soon came to the conclusion that credit stringency was developing too far and too fast. I have a strong impression that this course of events had much to do with the decision by the monetary authorities to reverse the trend of credit developments earlier than might otherwise have been the case. It is ironic that the Federal Reserve authorities, having striven for a full seven years to inaugurate a more restrictive interest rate policy in the face of determined and for the most part effective Treasury opposition, suddenly became faced with the opposite situation: a Treasury policy which now became too restrictive too rapidly. The result, thus largely fortuitous, was that the monetary authorities were able to establish a record of reversing monetary policy at the peak of the boom much earlier than they had succeeded in doing at any other point in history.

Unfortunately, much of this commentary must remain in the realm of speculation. The only thing that we can say definitely from the facts as they emerged is that the monetary authorities avoided overtly adding to credit stringency during a three-months period near the very end of the boom, and substituted for this essentially neutral policy a policy of active credit ease well in advance of any real evidence that the downturn was at hand. It may well be that the least fortunate result of the general rise in interest rates during the first half of the year was that growing scarcity of funds available for federally guaranteed mortgages resulted in a rise in interest rates in this area. This not only confused the picture as to whether the government was seeking to raise interest rates generally or to lower them, but may represent a substantial long-term cost to such borrowers, since the higher rate has remained in effect in spite of easier money market conditions. From the standpoint of its impact upon spending as a whole, however, the effects of the change in mortgage rates do not appear to have been serious, since construction has remained remarkably strong.

Monetary policy since mid-1953 requires little comment, the Federal Reserve System having followed an active policy of easing credit by means of reduction of reserve requirements, purchases in the open market, and two reductions in the rediscount rate. The extent to which these policies have contributed directly to the leveling out of the economic decline since earlier this year is of course uncertain; but the actions taken have at least been conducive to recovery.

With regard to the longer run, it appears to me that Professor Roose's questions concerning our ability to maintain high level employment, in view of our increasing labor force and of improvements in productivity, are well founded. Those who look to private investment for the necessary increases in the spending level are likely to be disappointed. Aside from inventory changes, gross private domestic investment has been remarkedly stable over the past three years—and remarkably high. Although we have been experiencing an unusual period of rapid technological advance and very high construction, it does not seem reasonable to expect these factors to expand further rapidly enough to take up the slack. Consumption, as Professor Roose has pointed out, could not be expected to provide much of the required increase, even if we assume a substantial drop in the rate of saving. With these points in mind, one might raise a serious question as to the efficacy of this year's tax reduction program, so largely based on the "trickle down" theory of demand stimulation.

The remaining factor is therefore government spending, whose sharp decline in the past year has so vitally affected aggregate demand. To the extent that world conditions permit a reduction in defense expenditures, it might be useful to think in terms of government spending for such items as highways rather than a further reduction in over-all government expenditures. Under present conditions with respect to revenue, this would raise the familiar question of the trend of public debt—surely too complex a question for our present limited discussion.

DEBT MANAGEMENT AND MONETARY POLICY

FEDERAL DEBT MANAGEMENT: CIVIL WAR, WORLD WAR I, AND WORLD WAR II

By Marshall A. Robinson
Dartmouth College

The tools of public debt management used in each of our major wars fall into three broad categories. First, the government has created securities in a variety of forms. The interest rates, maturities, conditions for call or redemption, and other special provisions (including taxability) have been adjusted to fit various requirements. Second, the government has, to some extent, manipulated the market. In some cases this has simply been an advertising program, but more frequently it has been a high-pressure campaign playing on the emotional tension of the times. More important in recent years have been the somewhat mechanical techniques for rigging and underwriting the market. Third, the government has used powers of compulsion ranging from the thinly veiled threats of quotas to the declaration that certain of its securities are legal tender (i.e., money).

A variety of objectives have guided the use of these tools. Most economists have urged the debt authority to use them primarily as weapons for the control of inflation.[1] But the debt authority is also asked to finance large deficits without paying excessive interest costs, without establishing "unmanageable" postwar debt structures, without treading too harshly on our concepts of free markets, and without injuring the future ability of the government to borrow. The result has generally been a series of compromises, with service first to one then to another objective. As a result none of the goals has been fully achieved, nor completely disregarded.

The Civil War, World War I, and World War II did not impose equal burdens on the debt authority. Some indication of the different magnitudes of the financing problem is shown by Table 1. In terms of the diversion of resources to war, World War II was about four times as costly as World War I. The share of war costs financed by taxation in the Civil War was about half that of World War II. Furthermore, variations in the length of the war emergency, the degree of popular support for the war, the characteristics of the monetary system, and the distribution of the tax burden also influenced the magnitude of the

[1] The lack of unanimity among economists on this issue probably stems largely from disagreement on the desirability of direct controls. Faith in the effectiveness of direct controls for controlling inflation (plus, in some instances, a hope for a moderate degree of inflation) encouraged emphasis of other objectives, especially in World War II.

task of the debt authority. Nevertheless, in each of the wars the Treasury was faced with the task of channeling to itself large amounts of money in short periods of time. This pressure to maintain a rapid flow of funds is a distinguishing characteristic of wartime debt management. The following discussion of debt management practices examines some of the things the Treasury has done to meet this pressure.

Marketing the Securities. In each of the wars advertising campaigns stressed the patriotic duty of citizens to buy bonds, and in many cases the appeal to unsophisticated investors was based on a presumed need for funds for specific purposes ($18.75 will buy a grenade for our boys). The organization developed by Jay Cooke during the Civil War established the general pattern used in subsequent campaigns. Relying primarily on banks and other financial institutions as the focal points for local committees, he brought the sales message to every community. With the development of mass communication media and more scientific methods of calculating quotas, sales policies became more centralized but the core of the sales program has remained a voluntary "grass-roots" approach.

In wartime, the need to sell government securities to groups unfamiliar with investing requires that efforts be made to simplify the process. "Three will get you four in ten years" was one way to simplify the idea of compound interest. It was probably only exceeded in its simplicity by the "two cents a day" slogan which was used to sell the 7.3 per cent notes of the Civil War. Similarly, smaller denomination

securities have been offered to persons with low incomes. The development of the saving stamp scheme during World War I was the logical development of these efforts. The "withholding" program of the payroll savings plan of World War II was another such step designed to simplify and widen the distribution of government securities.

Preventing the Postponement of Bond Purchases. One obstacle to the sale of bonds during wartime is the reluctance of persons to invest because they expect bond prices to fall as the war continues. In October, 1942, this attitude apparently contributed to the near failure of at least one bond offering. But for the rest of the war the problem was eliminated by the clear understanding that the Federal Reserve System would protect the yield curve existing at the beginning of the war.[2] In World War I the Treasury had used the conversion privilege on the first two Liberty Bonds, saying, in effect: if bond prices fall, holders will be able to turn in their old bonds at par for any new bonds with higher coupon rates. By placing certain time limitations on the right to convert, by changing the tax-exemption privilege, and by naming the last loan a note instead of a bond, it restrained some of the conversion. Nevertheless, two-thirds of the convertible bonds eventually ended up in a form which dissipated the potential savings of the early low interest rates.

The Interest Rate "Trade." When upward pressure on interest rates becomes strong, the Treasury can relieve it by monetizing a portion of the debt. Later comments will show that the Treasury has made considerable use of this safety valve. But this is not the full extent of its efforts. It can also vary the security package by offering other types of yields.

Tax exemption has been the nearest alternative to the reward of higher interest rates. It was not used during World War II—except for the *de facto* exemption given to some holdings of savings bonds.[3] In the Civil War, tax exemption was probably not especially effective in in-

[2] The serious problem of postponed bond subscriptions was eliminated, although not everyone fully believed that the pegs would hold. The doubters were a good market for short-term, low-yield securities and, as Paul Samuelson put it, "the gullibility of investors" yielded a benefit to taxpayers. See his, "Turn of the Screw," *Am. Econ. Rev.*, September, 1945, pp. 674-676. Without this uncertainty the pegs probably would not have held. An interesting discussion of the disequilibrating effect of certainty in a supported market is found in Elinor Harris, "Money Demand and the Interest Rate Level," *Quart. Jour. Econ.*, February, 1950, pp. 105-124; also "Comment" and "Reply," *Quart. Jour. Econ.*, May, 1951, pp. 284-289.

[3] Since the large mass of holders of E-Bonds probably do not report the interest in their income tax return they may be considered, in effect, tax-exempt issues. For the same reason many savings deposits, savings and loan shares, and other widely distributed financial assets may also be considered tax exempt. However, it seems doubtful that this type of exemption was important to the people (small investors) who received it. Of course, if the Treasury had, at the time of sale, pledged a stronger enforcement of tax reporting for E-Bonds than other exempt assets, the attraction of E-Bonds would have been weakened.

creasing the demand for securities. The maximum income tax rate was only 5 per cent; so that at best the difference in yield was minor. More important, though, the exemption feature was not especially attractive because it was written into the revenue law instead of the security itself: it was only as good as the current revenue law.

Tax exemption was an important variable during the first World War. After the First Liberty Loan (which was fully exempt except for estate and inheritance taxes), a variety of exemption provisions were used. In the second and third loans, the Treasury increased the rate of interest and reduced the degree of tax exemption—partly in order to obtain a wider distribution of bonds with persons of moderate means and partly to prevent complete conversion of the first Liberty bonds. In the Fourth and Fifth Liberty Loans, the Treasury, attempting to halt the increase in interest rates, used one of the most interesting tax-exemption features known. This was the carry-back tax exemption through which, depending on the amount of fourth or fifth Liberty bonds held, additional tax exemption could be obtained on other Liberty bonds held. In other words, by purchasing the new bonds, investors could get tax exemptions for some of the previously taxable securities.[4]

In all of our wars, the government has attempted to substitute the appeal of patriotism for the appeal of high yields, but in none has there been as frank a recognition of this trade between better yields and patriotism as in World War I. Indeed, the excesses committed in the name of the war effort during World War I probably account in large part for the somewhat more relaxed approach used during World War

[4] The sequence was as follows (variations in exemptions applied only to graduated income and profits taxes):

First Liberties (3½%)—Exempt in unlimited amounts.
Second Liberties (4%)—Interest from $5,000 principal exempt
Third Liberties (4¼%)—Same as Second Liberties but total exemption from Second and Third Liberties could not exceed $5,000.
Fourth Liberties (4¼%)—Same as Third Liberties but total exemption from Second, Third, and Fourth Liberties could not exceed $5,000.
Except: (1) $30,000 of Fourth Liberties were exempt until two years after the war and (2) an additional amount of Second and Third Liberties equal to 1½ times the holdings of Fourth Liberties (but not over $45,000) were exempt for the same period.
Fifth (Victory) Notes
4¾%—No tax exemption.
3¾%—Exempt in unlimited amount.
In addition, Second, Third and Fourth Liberty bonds equal to three times the holdings of Victory Notes (but not over $20,000) were exempt.

Thus, in addition to the exemption of unlimited amounts of the First and Fifth (3¾ per cent series) loans, purchasers could also obtain exemption on $100,000 of Second, Third, and Fourth Liberty bonds, largely by the carry-back exemption. For a short description of the carry-back exemption, see Robert A. Love, *Federal Financing* (Columbia University Press, 1931), pp. 178-180; some Treasury reasons for this type of exemption are given in a letter reproduced in the *Annual Report of the Secretary of the Treasury* (1918), pp. 14-17.

II. The social pressure of patriotism coupled with quotas can be a ruthless and discriminatory device—especially for the economically insecure.[5] The official disapproval of coercive patriotism during World War II can be contrasted with the statement, attributed to Charles G. Dawes, then chairman of the regional sales campaign, when someone expressed doubt that a 3½ per cent interest rate was high enough: "Anybody who declines to subscribe for that reason, knock him down."[6]

But if patriotism as a substitute for interest payments was deemphasized in World War II, its place was more than filled by another feature: liquidity. If money is defined in terms of the two attributes of standard of value and medium of exchange, there is a clear demarkation between money and debt. However, when stress is put on the first attribute and its subcharacteristics—a store of value and a bearer of options (the stress indicated for contingency and speculative balances)—the distinction between money and debt becomes hazy. Assets of the hazy type are ordinarily labeled liquid assets; their price in terms of the accounting unit is regarded as given but they cannot be spent. Debt management during World War II resulted in the creation of a large volume of such assets. In addition, assets were created which, though they lacked contractual stability in price, offered only minor prospects of variation and therefore only slightly less liquidity.

The nearness of the federal debt to money was fostered not only by the support program and the issuance of redeemable securities but also by emphasis on marketable short-term securities. Thus investors who were unconvinced of the tenacity of the support program and who were legally limited to a given amount of savings bonds could still find an ample volume of liquid securities in the short-term market. Table 2 shows this greater emphasis on short-term issues during World War II.

With an upward sloping yield curve, the stress placed on short-term securities resulted in a substantial interest savings. In other words, the Treasury also "played the pattern of rates." But this source of Treasury economy does not appear to have been available in our earlier

[5] See Henry C. Murphy, *National Debt in War and Transition* (New York, 1950), pp. 86-87. Murphy notes that there was probably much coercion in bond sales during World War II. But the effect on the bondholder was, at worst, only temporary because he could get back at his oppressor by selling or redeeming his bond without a loss. In this he was better off than the bondholder in World War I, who in most cases would have had to sell his bond at a loss.

[6] Quoted in C. J. Childs, *Concerning U. S. Government Securities* (Lakeside Press, 1947), pp. 119-120. The idea of a trade between interest rates and patriotism runs through many Treasury releases during this period. For instance, referring to the last Liberty Loan, Secretary Glass said: "Some students of the situation believed it would be impossible again to appeal to the patriotism of the American people. The Treasury held no such view. Furthermore, it was impossible to float the loan strictly on a commercial basis." *Annual Report of the Secretary of the Treasury* (1919), p. 33.

wars. The yield curves during World War I and the Civil War are not clearly defined, but they seem to have been virtually flat throughout the war; hence little interest saving was to be gained by using short-term issues.[7]

Although short-term obligations have been used in all of the wars, they were not generally considered respectable before World War II. In World War I, Treasury certificates were generally issued in anticipation of taxes or bond subscriptions. They were used for later pay-

† Includes issues which possess a definite maturity date, e.g., savings bonds or notes, but which are payble upon demand of holder.

ments to the government and were never really considered a permanent part of the debt. In the Civil War, the substantial use of three-year notes (and bonds callable in five years) was rationalized by the Treasury as a means of retaining control of the debt. Interest rates were expected to decline and the government was expected to retire some of the debt in the postwar period; hence it was deemed desirable that a portion of the debt be subject to refunding. Nevertheless, the objective at the time was still to refund the short-terms into long- and this was done shortly after the war. On the other hand, the greater emphasis during the thirties of the liquidity needs of financial institutions and nonfinancial corporations led to greater acceptance of short-terms and

[7] In World War I, the basic yield curve for high-grade corporate securities was flat in the first year of the war and slightly downward sloping to the right in 1918 and 1919. See David Durand, *Basic Yields of Corporate Bonds 1900-1942* (National Bureau of Economic Research, Technical Paper, No. 3, 1942), p. 5. Since the spread between corporate and government securities probably varied from time to time and for different maturities, this yield curve is only a rough approximation of the government's curve. A sampling of government security yields during the Civil War suggests the same thing: a flat curve with a slight tendency toward higher yields for short-terms.

permitted them to play a permanent part in the "tailoring" program of World War II.

Maintaining the Prices of Government Securities. The problem of maintaining the prices of outstanding securities can be evaded through the use of fixed price, demand obligations such as the Series E bonds used during World War II, the War Savings Certificates (which were redeemable upon ten days' notice) used during World War I, and the Temporary Deposit Certificates (redeemable on ten days' notice) used during the Civil War.[8] Such demand obligations were only used to a minor degree in World War I and the Civil War. But in financing World War II, against a background of uncertainty caused by the depression, it apparently seemed unlikely that anything less than a completely safe security could attract a large volume of small savers' funds. Thus fixed price obligations accounted for over one-fifth of the World War II debt.

The efforts of the debt authority to maintain prices of government securities in the market have received considerably more attention than these contractual agreements to pay a given amount on demand. Manipulation of the prices of outstanding securities is a familiar technique of bond sellers—and the Treasury is no exception. When the Treasury is able to hold the market prices of existing securities at or above their issue price, two results are achieved. First, it prevents the investor from finding better, cut-rate securities on the open market, and, second, it indicates to the public that the purchase of a government security will not involve a direct capital loss. In this regard the support program of World War II was clearly a success.

In contrast to World War II, the support operations of our earlier wars were crude and ineffective. In the Civil War, the Treasury commissioned its agent to enter the market on several occasions to purchase issues which, because of their low prices, were discouraging the sales of current offerings. The largest of these support operations involved only 10 million dollars and apparently took only the biggest bargains off the market. They were solely emergency operations designed to deal with specific market situations and the authority to purchase securities was never continued for more than a month or two at a time.[9]

[8] The Temporary Deposit loan of the Civil War was an interesting excursion by the Treasury into the banking business. These deposits, made at the subtreasuries, paid 4, 5, and 6 per cent interest at various times. Virtually on a demand basis, they were attractive to banks and other financial institutions for investment of short-term funds. The certificates ultimately came to be used by city banks for settling clearing house balances. In the type of funds they attracted and the way they were used they were similar to the Treasury bills of World War II.

[9] An interesting source of price support existed with the gold bonds of the Civil War. Since the market price of gold rose at almost the same rate as the general price level, bondholders receiving interest in gold and a pledge of redemption in gold had what amounted to a "purchasing power bond." The price of gold bonds reflected this by stay-

During the first World War, several devices were used directly to support the prices of government securities. Beginning with the Third Liberty Loan, the Treasury was authorized to set aside 5 per cent of the proceeds of new bond issues for the purpose of repurchasing securities, the maximum price to be paid for these securities was par plus accrued interest, and the securities purchased were to be canceled and considered retired. In the first six months in which this program was in effect the Treasury purchased close to 250 million dollars worth of Liberty bonds and by November, 1919, it had purchased 953 millions.

This type of support operation was, in effect, simply a preliminary repayment of the portion of the loan which appeared to be excessive (excessive being defined as that marginal amount of the loan which tended to depress the market price below some predetermined level). It meant that the Treasury had to borrow more funds in other loan drives or concurrently sell some other type of security. In a period of rising interest rates, it meant that the Treasury was in effect refunding a portion of the outstanding debt at higher interest rates.

Repurchase of Treasury securities was also made possible in World War I by the establishment of the War Finance Corporation (WFC). This agency obtained most of its funds from the Treasury and purchased government securities for its own account and then later sold them to the Treasury. Since WFC held 487 millions in November, 1919, the total amount purchased by the Treasury by that date was 1.43 billion, or 5.8 per cent of the war debt.

This "by its own bootstraps" operation, in which the Treasury used mainly borrowed funds for the purpose of buying its own securities, was not wholly successful if the maintenance of prices at par is taken as the criterion. Except for the First Liberty Loan, each of the Liberty bonds fell below par from the first time they were traded and gradually moved down in price for several years. But, obviously, par need not be taken as the sole measure of success, since we have no way of knowing how far prices might have fallen without these operations. It is interesting to speculate, however, whether the government would have

ing above par, but the full impact of the inflation never showed in bond prices. If it had, bond prices should have increased with increases in the price of gold. (To maintain a constant yield the price of a gold perpetuity would be a constant multiple of the price of gold.) Since increases in the price of gold were also interpreted as indications that the government might not continue to pay in gold, a prospective purchaser could not view the bond as a pure purchasing power bond. Nevertheless, for those persons who bought them at par and held them through the inflation they were almost as good. Interesting comments on this aspect of the Civil War gold bonds are found in Wesley Clair Mitchell, *History of the Greenbacks* (University of Chicago Press, 1903), pp. 275-279, 377-378; also, Frederick R. Macaulay, *The Movements of Interest Rates, Bond Yields, and Stock Prices in the United States Since 1856* (National Bureau of Economic Research, 1938), pp. 201-203.

helped itself more if it had sold 1.5 billion dollars fewer bonds and forgotten all about trying to support prices.

The pressure of declining security prices intensified as the war progressed and in the initial version of the Fourth Liberty Loan Act the ultimate solution was offered: a provision giving the President the power to prohibit the transfer of bonds on the market. After much debate, the provision was softened so that the President could simply investigate and regulate sales. Apparently scant use was made of the power to subpoena books and testimony, but there is ample evidence that the Treasury employed its powers of persuasion in the market place. Treasury Department statements made it quite clear that the government considered bond buyers as patriots and people who sold their bonds were frequently the opposite—although they were never quite called traitors. In contrast with these sometimes tortured devices of World War I, the simplicity of the support program of World War II seems almost benign.

Monetization of Debt. In a sense, the amount of the debt which spills over into the monetary system is a measure of the effectiveness of all the rest of the debt management policies. That is, the monetized debt may be considered a residual: what is left over after other sales efforts had been used. The public record clearly shows that our wartime debt authorities have regarded monetization of the debt in this way; they considered monetization to be undesirable and they attempted to avoid it. But it is important to recognize that the other residual market (remaining nonbank funds) still existed and could be tapped with the residual tools—greater sales efforts, higher interest rates, more tailoring, or further effort with any of the other flexible sales weapons. The fact that these other tools were not used suggests that monetization was considered a more flexible, more certain, or less costly tool than the others.

In World War II the approach was fairly simple: the objective was to sell as many securities as possible, with the weapons used, outside of the banking system and then to sell the balance to the banks.[10] In order to perpetuate this arrangement, the Federal Reserve System and the Treasury developed the support program. And to further implement the program they employed a new tool of war finance: the yield curve. With this ingenious device, deviations from

[10] In a formal sense, only purchases by the central bank are inflationary. Sales of government securities to commercial banks do monetize the government debt, but if the supply of reserves is given, government debt is simply substituted for private debt. However, when the central bank keys its purchases (or advances) to commercial bank purchases, i.e., more commercial bank purchases result in more central bank credit, then sales to banks are inflationary. Since commercial banks had and used the privilege of shifting securities to the central bank during each of the world wars, sales to them are considered inflationary here.

the normal yield curve were the trigger mechanism for the creation of new bank reserves. From the standpoint of simplifying the task of debt management, this program was a major advance in war finance. It permitted the Treasury to develop a basket of securities which bore certain well-defined characteristics and to use these same securities with minor changes for the duration of the war. In contrast, the securities of our other wars had been continuously sprinkled with a variety of special "this time only" provisions.

As shown in Table 3, the Reserve banks purchased close to 9.6 per cent of the debt of World War II. In World War I they had purchased only about 1 per cent. But whereas Reserve bank loans secured by government securities were only 0.1 per cent of the new debt in World War II, they were equal to 6½ per cent of the debt of World War I. Thus Reserve bank credit on account of government securities amounted to 9.7 per cent of the World War II debt and 7.4 per cent of the World War I debt.

In World War I, a preferential discount rate on notes secured by government securities was the major device employed to expand Federal Reserve credit; in World War II open market operations accomplished the same thing while at the same time registering distinct price quotations in the government security market. These means used to expand Federal Reserve credit reflect the prevailing theories of monetary controls. In 1917 the discount rate was the core of Federal

TABLE 3

BANK CREDIT AND FEDERAL DEBT, WORLD WARS I AND II

(Amounts in billions of dollars)

	WORLD WAR I June 1916–June 1919		WORLD WAR II June 1941–Dec. 1945	
	Amount	Percentage of Total War Debt	Amount	Percentage of Total War Debt
Total war debt	$24.26		$229.15

Reserve policy; open market operations as a means of influencing the volume of credit were still to be invented. In 1941 the situation was reversed; open market policy was considered paramount and the discount rate was regarded largely as a psychological tool.[11]

About one-third of the debt created during each of the world wars was financed by commercial bank credit. In the second World War the banks purchased 31 per cent of the new debt for their own portfolios and carried an estimated 3 per cent by loans to customers. In World War I, the banks purchased only 18 per cent on their own account and extended loans to customers for approximately 12 per cent more of the war debt.[12] Financing of the deficit by commercial bank credit can be roughly set then at 30 per cent in World War I and 34 per cent in World War II.

In World War I a greater share of the new reserves was used to extend credit to customers under the "borrow and buy" program. This, of course, was more in keeping with the then prevailing ideas of banking. The customer loan was considered more liquid than the security which it purchased. By World War II, banks had become accustomed to larger government portfolios; new means of liquidating securities had been developed; a bank could afford, therefore, to invest more heavily in governments. The fact that the Treasury provided a stable market and a host of varying maturities, enabling a bank to pick its liquidity risk, was clearly more conducive to direct holdings than the emphasis on illiquid long-term securities of World War I.

A comparison of the monetization of the debt in the world wars with that of the Civil War shows the contrast between types of monetary systems. The first Civil War loan, which was taken by a group of large banks, contributed to the suspension of gold payments by the banks and eventually by the Treasury. Into this monetary vacuum the Treasury issued its first series of greenbacks: legal tender notes.

[11] Anna Youngman suggests a number of factors which may account for the shift in techniques: the development of the tradition against borrowing and Federal Reserve disapproval of borrowing as a long-run source of reserves, the excess reserve episode of the thirties, and bankers fear of being trapped, as they were in 1920, by rising discount rates. See her *Federal Reserve System in Wartime* (National Bureau of Economic Research, Occasional Paper No. 21, 1945), pp. 26-29. Of course, banks were trapped in 1920 by a reversal in Federal Reserve policy. And the same thing could have happened following World War II if open market policy had been reversed.

[12] Two points have been raised about the customer loan data: (1) some customer loans secured by government securities may have been used to finance purchases other than government securities; (2) some government securities may have been purchased with loans secured by personal notes or other collateral. Regarding the first, such borrowers had a choice of selling their bonds or borrowing new funds; since they chose to borrow, banks did, in effect, finance their bondholdings. As for the second, there may have been a small amount of such lending, especially where customers already had established a line of credit; but the preferential borrowing rate generally accorded to loans secured by governments undoubtedly kept most such bank credit in the "secured by government obligations" classification.

Subsequently, the issues of greenbacks, demand notes, and fractional currency rose to nearly 460 million dollars, or about 17 per cent of the total war deficit. In addition, the Treasury also issued over 225 million dollars of one-, two-, and three-year legal tender notes which paid 5 per cent and 6 per cent compound interest. The 5 per cent notes bore coupons which could be clipped, eliminating any interest accrual.[13] They were therefore widely used as currency. The three-year compound interest notes were an attempt to correct this situation by allowing interest to accrue for the whole period to maturity (after three years a $100 note had a redemption value of $119.40). Approximately 8 per cent of the war deficit was financed by this interest-bearing legal tender.[14] In addition, by June 30, 1865, the national banks held 392 billion dollars in government securities of which 236 million was held on deposit with the Treasurer of the United States. Data on state banks' holdings of government securities are not complete but they probably did not exceed 25 million dollars by the end of the war. Altogether, then, it appears that national and state commercial banks absorbed about 15 per cent of the war debt.

These three categories of Treasury issues—legal tender notes, interest-bearing legal tender notes, and securities sold to the commercial banks—account for about 40 per cent of the wartime deficit. Thus in terms of monetization of debt, the Civil War falls in between the two world wars. However, because Civil War taxing policy was less vigorous, the monetized debt played a larger role in over-all fiscal management than in the two later wars.

Conclusions. The debt authorities during World War II employed more potentially inflationary devices than were used in either of the previous wars. Pegged securities, short-term securities, and redeemable securities were the core of the World War II program. This strong emphasis on liquid securities must be partly explained as a heritage of the depression. Hard-won low interest rates apparently could not easily be cast aside by the people who made them, especially since the same people also believed that the economy would return to prewar conditions. Thus time and again the Treasury explained its low interest rate policy by stressing the importance of low rates as a contribution to postwar full employment. But perhaps equally important was the fact that by 1942 a host of direct controls had been invented

[13] We can get a rough measure of the value to the Treasury of the legal tender provision at the time of issue by noting that these one- and two-year 5 per cent legal tender notes were issued at par at the same time that one-year 6 per cent certificates of indebtedness were selling at around 95.

[14] Of course the whole 225 million dollars did not circulate as money for the entire time it was outstanding. It seems likely that more of the compound interest notes circulated in their first year (1865) than later. Since the notes were spendable and had the legal status of money, they are included here as part of the monetized debt, though it is clear that only a fine line separates them from some of the nonmarketable issues sold during World War II.

and accepted. The use of direct wage and price controls and rationing removed a major obstacle to the development of the full-scale support program. These two factors—the presumption that inflation would not be a major problem after the war and, just in case, the development of tools to keep inflation under control—help explain the greater emphasis on liquidity in World War II debt policy. Subsequent events made this calculated risk wrong.

But if the calculated risk proved to be wrong, some qualitative gains were still made. Tax exemption with its resultant discrimination in favor of the wealthy was discarded (a difficult weapon to discard if the Treasury is to rely largely on the natural forces of the market). Vigilante subscriptions which act like a tax, without the careful equity considerations generally found in a tax, were virtually eliminated. And, although as it developed in World War II the total effect of the program of tailoring the securities to meet the needs of investors was inflationary, the principle of differentiated markets suggests a more equitable debt structure than the policy of fitting most investors to Liberty bonds.

Broadly speaking, the government is faced with two alternatives in financing a given wartime deficit. First, it can use money and near-money and then rely on a variety of direct controls to restrain inflation. This was the emphasis of the policy followed during World War II and when controls were discarded following the war the inflationary potential was revealed. Second, by using forms of compulsion and/or securities bearing sufficiently high interest rates the Treasury can induce or force the public to give up liquidity. This policy was stressed more in the debt management of World War I. The first alternative would be used where low interest rates, stable bond prices, moderate sales efforts, and direct controls are considered desirable or at least unobjectionable. The second would be used where control of inflation is considered the paramount objective and where continued direct controls are considered objectionable or politically unobtainable.

The central bank may reverse the illiquidity implicit in the second approach when the threat of deflation looms. Open market purchases should be sufficient. But the ability of the central bank to remove the liquidity implicit in the first approach may be severely limited by the composition of the debt. Contractual near-money, such as redeemable bonds and short-term securities, cannot easily be destroyed by the monetary authority. Indeed, there is the possibility that attempts to restrain the "moneyness" of a portion of the debt (say, by dropping pegs) would result in the creation of even more money.[15] The implica-

[15] Of course, if the central bank is willing to completely cut loose from the Treasury, contraction would be possible. But seemingly the more the debt is floating, the more the

tion seems clear that if the debt is to aid in the control of inflation it must consist of securities which are subject to attack by the monetary authority (ideally, consols). In this regard the debt management of World War I was considerably more successful than that of World War II.

But before approving a future war program based primarily on consol-like obligations, several familiar objections must be raised. Could such instruments be sold? Would it be desirable to attempt to distribute such securities widely and permit the repercussions of changes in monetary policy to bear directly on small bondholders as well as large? Would wide distribution of central bank ammunition in this kind of a political system constitute a practical restraint on the use of contractive monetary policy? Answers to these questions are far from obvious (nor do these questions cover all the problems of using consols) but they all suggest one point for consideration; namely, that nonmarketable securities should have a place in a program for financing a future deficit. However, if such securities are used, it would be desirable to restrict the degree of redeemability considerably more than was done during World War II.

If during wartime the general appeal of nonmarketable securities with restricted redemption privileges would preclude a wide distribution, then some form of compulsory program may be necessary. A compulsory lending program tied to income or social security taxes and using, perhaps, a cost-of-living index to determine interest payments would if applied to a portion of the debt have the advantage of leaving the balance of the consol-like debt free to monetary manipulation. In this context of compulsion, even a security reserve program for banks and other financial institutions (and perhaps even nonfinancial concerns) might not appear inappropriate.

The assumption behind these comments is that the lessons of earlier debt management have demonstrated that the primary goal of wartime debt management should be to aid, not hinder, the control of inflation. Even more basically, they assume that debt management should help to distribute the cost of war in a more equitable manner than by inflation. But a "fight inflation at any cost" approach to debt management can, as we have seen, have its own harsh and inequitable aspects. The first task, then, in formulating a program for the management of future war deficits will be to make a clear-cut decision of what the objectives of wartime debt management really are. Once these objectives are established, the demonstrated inventiveness of the monetary and debt authorities should be adequate for the task.

central bank may be considered responsible for it. See Robert Roosa, "Integrating Debt Management and Open Market Operations," AEA *Papers and Proceedings*, May, 1952, pp. 214-235.

MONETARY POLICY IN RECENT YEARS

By Richard Youngdahl
Federal Reserve Board

Four years ago monetary policy was reinstated as a major measure of government policy for combating booms and depressions. Since then flexible monetary action has played a classical role in dealing with a complete business cycle.

This has also been a period of rediscovery and adaptation of the instruments of monetary policy. From long disuse, the workings of the instruments for general credit regulation had become unfamiliar to the financial and business community. In certain respects, moreover, changed circumstances called for changes in the techniques of their use, although in general old concepts and principles have proved remarkably appropriate to the postwar world. Debt management policies and techniques have also been worked out which help to keep the financing requirements of the federal government from tying down monetary policy and to reinforce monetary policy with debt management actions.

It is the primary purpose of this paper to consider how the three major instruments of general credit policy were actually used in a co-ordinated program looking alternatively toward credit neutrality, restraint, and ease over the period since March, 1951. Open market operations and, in a supplemental way, changes in reserve requirements are the principle means available to the monetary authorities for making available the reserve funds needed to support economic growth while maintaining whatever degree of pressure on bank reserve positions may be considered appropriate to the prevailing economic situation. Reserves not supplied by these instruments are available at the initiative of individual member banks through borrowing at the Reserve banks. When reserve funds are obtained this way, however, banks are obliged to repay and tend to restrict their credit extensions in order to do so.

During most of the period under review, the degree of pressure on member bank reserve positions seems to be most usefully indicated by the volume of member bank borrowing. Another indicator—the volume of unborrowed excess reserves or free reserves—might perhaps be used more appropriately in periods of extreme credit ease because the volume of borrowing cannot become negative. For purposes of this discussion, however, I shall keep to a single indicator: the volume of borrowing.

Revival of Discount Function after the Accord. With the Treasury-Federal Reserve accord in March, 1951, a major restrictive step was

taken in permitting prices of government securities to find their own levels in the market, without open market action by the Federal Reserve to establish them or directly affect them. This action stripped excess liquidity from the economy. It reinstated in the market a distinction between shorter and longer term securities; that is, between securities of little market risk and those of greater market risk. It made it desirable, in fact, to permit a fairly sizable growth in the volume of bank credit and money over the ensuing year or more in order to cushion the force of the policy change.

During this interval general techniques of monetary management which had been dormant for two decades were brought back into use. Most important was the resumption of co-ordinate use of open market operations and the discount mechanism to achieve whatever conditions of supply, availability, and cost of credit were considered appropriate to the developing economic situation. Open market operations became again the instrument for influencing on a current basis the over-all volume of unborrowed reserves of member banks. When policy-making officials believed there was need for restraint on bank credit and monetary expansion, less reserves were made available on an unborrowed basis, thereby obliging banks as a whole to increase their borrowing if they were to expand credit. When easier credit conditions were desired, open market operations were used to reduce the pressure of indebtedness on banks by increasing the volume of reserves available from sources other than borrowing.

The extent of member bank borrowing affects bank lending and investing because individual banks are generally reluctant to remain indebted to the Federal Reserve for more than a temporary period. Indebted banks endeavor, therefore, to make adjustments in their total loans and investments to whatever extent may be necessary for the repayment of their borrowings. When indebted banks make these adjustments, they of course shift at least part of the reserve deficiency to another bank, and that bank will in turn need to borrow and make subsequent asset adjustments to repay.

This shifting among banks of the burden of borrowing at the Federal Reserve tends to make the Federal Reserve discount rate effective. At such times the discount rate becomes the pivotal rate in the money and capital market, and money rates tend to array themselves in relation to the discount rate. In a technical sense, this relationship tells banks whether it is cheaper to borrow or sell securities for a short-period adjustment. When through open market operations member bank reserve positions have been put under pressure (or allowed to get under pressure as bank credit and deposits expanded), money rates tend to range higher in relationship to the discount rate. As bank re-

serve positions ease, market rates will be lower in relation to that rate.

In the postwar world the liquidity positions of banks and of other institutional lenders have been largely involved in the government securities market. In the short- and intermediate-term sector of that market, banks are a major, and generally the dominant, factor. When banks have developed reserve deficiencies and are obliged to borrow, they commonly seek to repay borrowing initially by sales of short-term government securities. When such selling pressure is increasing, yields on short-term government securities tend to rise. Banks under these conditions may also become sellers of intermediate-term and longer issues, or at least will be less interested in buying, and these yields will also tend to go up. Such a development then will affect not only the liquidity of banks but also the liquid position of savings institutions of various kinds because of the reduced value of their sizable holdings of intermediate- and longer-term government securities. Pressure or ease in bank reserve positions is thus reflected rather promptly in the tone of the entire credit market.

When open market operations are being used so as to develop restraint on credit expansion, it will become appropriate at some phase to supplement the action by an increase in the discount rate. This move will strengthen the reluctance of member banks to remain indebted to the Reserve banks by making current borrowing more expensive and probably by lending support to expectations of discount increases yet to come. Conversely, when credit conditions are being eased through open market actions designed to reduce the volume of member bank borrowing, a reduction in the discount rate will help relieve banks of the pressure to make even temporary adjustments in reserve positions in the short-term market rather than by use of borrowing at the Reserve banks. By changing this pivotal rate, moreover, the Federal Reserve exerts a strong influence on the cost of most other kinds of credit, since a rate change is an official recognition of a change in supply and availability conditions for credit that is likely to continue for a time.

In the four-year period since the accord, the interrelationship of the volume of member bank indebtedness, the general tone in credit markets, and the level of market interest rates in comparison with the discount rate have followed the pattern just outlined.

General Credit Measures, Mid-1951 to Mid-1952. During the first year after the accord, monetary policy was relatively neutral. There was a fair balance in the demand and supply of credit, given the credit and monetary expansion the Federal Reserve regarded as reasonable in view of the changed liquidity situation of the economy. Over the period, member bank borrowing at the Reserve banks tended to average

under 400 million dollars, except for the seasonal peak in December. Few, if any, individual banks remained long in debt to the System, but a number were alternately in and out of debt. With this general level of borrowing, the Treasury bill rate remained somewhat under the discount rate of 1¾ per cent, the yield on three- to five-year Treasury securities hovered around 2 per cent, and the yield on twenty-year Treasury bonds fluctuated under 2¾ per cent. Corporate and municipal security yields showed comparable stability and moved within a fairly narrow range.

Actually, during this period of about one year the stability in the general level of interest rates (although not of course in the interrelationship of yields on various types of credit) reflected largely the fact that banks obtained enough reserves from all sources other than by borrowing at Reserve banks to support a substantial bank credit and monetary expansion. This bank credit, added to savings available from nonbank sources, was sufficient to meet at stable interest rates the large credit demands coming to the money and capital market.

Credit Restraint, Mid-1952 to Mid-1953. Pressures of credit demand began to accelerate, however, in the second quarter of 1952 and over the following year, particularly with termination of controls over consumer credit and with the surge of activity that developed in the fall and winter. A vigorous expansion in private spending and in private credit demands developed just as defense outlays were reaching a peak and federal financing needs became exceptionally heavy. The rapidly rising volume of capital expenditures, inventory accumulation, and consumer durable goods outlays—to a large extent financed by credit—were contributing to overtime operations in industry and threatened to develop an unsustainable boom. Credit and monetary policy were turned toward curbing somewhat the expansion of credit and money, with the objective of preventing the volume of nonfederal spending from forming an extraordinary bulge in a relatively short period of time.

The Federal Reserve was not willing under these conditions to provide through open market operations the volume of bank reserves that banks wanted to support their lending activities. With increasing frequency individual member banks were obliged to go to their Reserve banks for temporary borrowing accommodation. As the volume of borrowing increased, member banks intensified their efforts to adjust asset positions so as to be able to repay. Growth in the volume of bank credit thus came under more and more restraint.

Increasing reliance by member banks on borrowing in the second half of 1952 was reflected in a rise in interest rates. Rates on three-month Treasury bills, which had been below the discount rate except

for an end-of-1951 peak, rose above it after mid-1952. Intermediate- and long-term rates also went up fairly steadily over the period. Early in 1953 the Reserve banks increased their discount rates. The credit market had partly anticipated this move in its prior rise, but the rate structure rearranged itself upward somewhat further in adjusting to the new discount rate of 2 per cent.

The volume of bank borrowing continued very large (about 1¼ billion dollars) during the early months of 1953, a season when bank reserve positions tend normally to be easy. Under this pressure, banks redoubled efforts to bring their reserve positions into line, and the rise in interest rates accelerated.

The rise in interest rates in early 1953 and the general tightening in credit availability did not, it should be noted, reflect an actual decline in the total amount of new credit available. It was due, rather, to an extraordinary bulge in the demand for a number of types of credit and the fact that bank credit was not permitted by the monetary authorities to increase by as much as would have been necessary to meet fully this increase in demand.

Credit Easing, Mid-1953 to Mid-1954. By midspring of 1953 monetary measures had made their contribution to preventing an excessive boom. Further monetary tightening was not needed from this standpoint, and developments in money and capital markets and in the economy generally indicated that if further tightening did occur it might cause unnecessary adjustment difficulties in coming months. Credit demands remained intense, but part of the demand was not for immediate use but in anticipation of needs by borrowers who wished to be certain their future requirements would be covered. Accordingly, measures were taken in May and early June to prevent the prevailing intense demand for credit from being reflected unduly in further tightening in the cost and availability of credit and further decline in the capitalization factors of the economy.

Open market purchases were made at that time in sufficient volume to reduce materially the volume of member bank borrowing at the Reserve banks. Reserve requirements were also reduced at midyear. Bank borrowing at the Reserve banks, which in the first four and a half months of the year averaged over 1 billion dollars, was reduced about one-half by the latter part of May and in June and July averaged just over 400 million dollars.

With this easing in the volume of member bank borrowing, both short-term and long-term interest rates declined sharply. By August, Treasury bill yields had declined to the discount rate. Comparable declines from June peaks occurred in yields on intermediate- and long-term securities.

Thereafter, as evidences of slackening in business activity began to accumulate, additional actions were taken to ease the credit situation. Over the summer and fall of 1953, in a succession of steps, credit became cheaper and more readily available. Member bank borrowing continued over the second half of 1953 to average between 400 and 500 million dollars. Interest rates declined steadily over the period.

In January, 1954, and in subsequent months, open market operations were so conducted as to eliminate virtually all member bank indebtedness at the Federal Reserve banks. This condition was maintained over most of 1954 by a succession of open market actions supplemented in midyear by another reduction in reserve requirements. In addition to the decline in borrowing, excess reserves of member banks rose somewhat through the spring and summer following a period of a number of months of stability at around 700 million dollars.

Reflecting the easy reserve position for member banks, market yields went down further and short-term government yields largely lost contact with the discount rate. Reductions were made in the discount rate in February and April, but these probably had little immediate impact in the market since the need for borrowing seemed remote for most banks. More recently, however, with the advent of seasonal credit and money pressures, borrowing has been somewhat more important, and short-term yields have moved into closer touch with the discount rate.

Throughout the year 1954, demand for long-term credit has continued very strong, reflecting large increases in mortgage and state and local government financing which more than offset some declines in the sales of new securities by corporations. Demand for short-term credit by businesses and consumers has been slack. Nevertheless, there has been a substantial growth in bank credit and deposits, due principally to expansion in bank holdings of US government and state and municipal securities.

Monetary Policy and Debt Management. For co-ordinated use of open market and discount policy in an anticyclical program, certain debt management conditions need to be fulfilled. Above all, open market operations must be free to operate as needed to offset changes in the various factors affecting bank reserves. Since there is no reason to believe that these operations will coincide in timing or direction with Treasury refinancing periods and considerations related to these activities, it is important that Treasury refinancing operations be handled in a way that will not require assistance from open market operations. By experimentation over the two or so years following the accord, refunding techniques were worked out that have proved highly successful from the standpoint of both the Treasury and the Federal Reserve.

The effectiveness of monetary policy is improved when the maturity of the federal debt is well spaced over a span of years. When this is the case, credit tightening and credit easing actions will be transmitted more smoothly and promptly throughout the credit market as these actions play on the liquidity of government security portfolios of banks and other lenders and investors. At the same time, however, there should be a large enough volume of short-term issues to support a broad money market adequate to meet the basic liquidity needs of the Federal Reserve System, banks, other financial institutions, and businesses. Progress has also been made in these aspects of debt management.

Summary. In summary, it may be said that during the past four years reserve banking techniques which were developed in this country during the twenties have been revived and used in more or less the fashion of that earlier period to achieve a contracyclical credit and monetary policy. In some respects, however, adaptations have been needed in these techniques to fit them into the present-day institutional framework. The major new fact in the postwar credit world is the existence of a huge government debt. Contrary to widespread fears, however, the size of the debt has not proved an unsurmountable obstacle to a flexible credit and monetary policy and in important respects has been helpful in implementing that policy. In general, the old instruments and principles of reserve banking have again proved themselves in use to be effective and sound.

DISCUSSION

ALBERT G. HART: Professor Robinson's paper affords a very interesting review of wartime debt management. As he points out, such a retrospect is useful above all as background for stand-by planning of economic mobilization—which like all such planning contemplates the possibility that a future war (which could start only because somebody hoped for a *Blitzkrieg*) might again become an endurance contest. Rather than blur the effect of his paper by dwelling on its rather minor flaws, I propose to sketch some of the contingent problems of any future war finance program.

Perhaps the chief lesson from the history of war finance is the tendency of a borrowing program to get diverted from its true aim of stimulating saving into the scoring of purely token triumphs, with distribution of kudos to the manipulators of empty symbols. Imposing bond subscriptions are financed painlessly (even with "free-riding" profit) by people who put themselves in funds by selling previously-bought securities to banks. Savings bond purchases are designed to pick up funds the buyers do not aim to spend, and the savings-stimulating effect of any underestimate of future spending is offset by easy redemption. Tax exemption is made available as a reward for switching assets. In any event (under the pattern of World War II), the incentive effect of tax exemption is frittered away. By failing to promise tax exemption but yet not setting up any efficient machinery to collect taxes on income from savings bonds, we managed to incur the costs of exemption *ex post*, without having it taken into account in savings decisions.

In any future inflationary squeeze (whether due to war or to the more probable event of another sudden bulge in defense spending short of war), a major handicap to policy will be the existing mass of liquid assets. We seem to have inflated ourselves up to the existing mass of currency and checking deposits. But either bond drives or compulsory lending programs will be ineffective if savings bond redemption and bond market support enable asset-switching to pass for saving.

Against this difficulty there are two possible remedies. One, as shown by Shaw and his associates, is to generate saving by drastic rationing of the privilege of spending, cutting existing liquid assets off from the market by some such device as issuing a new "ration currency" and freezing assets. If such a purchasing power rationing system were thoroughly applied, it might both generate the needed current savings and permit the immobilization of those savings. But the struggle to capture scarce goods by making side-payments out of supposedly immobilized assets would be intense. In enacting such a novel program, Congress would instinctively create major loopholes—particularly in a short-of-war situation.

The more orthodox remedy would be to overcome excess liquidity by monetary policy. To reduce the switching problem to manageable proportions, debt policy can work itself into a position where the bulk of nonbank holdings are in long-term marketable bonds. This can be done even in a recession if the authorities are willing to incur interest costs. True, to put more of a refunding into bonds has some deflationary effect; but not more than could

be offset by monetizing a minor fraction to give banks excess reserves. A mixture of bonds plus a little cash, in short, would be much the same in the short run as a mixture of notes and certificates. But in a future inflationary emergency, holders could be frozen into bonds much more effectively than into notes and certificates by permitting yields to rise somewhat. Thus the much-maligned policy of lengthening maturities, if carried out with resolution, could set the stage for a restrictive policy without having short-run restrictive effects.

In case an inflationary emergency develops, monetary policy could do much more than in World War II. In the nature of things, a rationing system would be necessary and would do much of the immediate job of generating savings. Monetary policy could help by encouraging installment buying of bonds (as distinct from lump-sum loans designed to be liquidated by selling the securities). Savings bonds could be given much less liquid redemption pledges. It would be much better after the emergency to have 50 billion dollars of genuine long-term bonds outstanding rather than 60 billions of nominally long-term bonds whose holders could and would redeem them freely. (Our so-called "ten-year" savings bonds have worked out on the average more like three-year notes.) Such a policy would involve higher interest costs and greater discounts on marketable bonds than that of World War II; but it would be much more conducive to saving during and after the emergency. If by any chance there were a tendency to stagnation later on, the government could always restore more liquidity than it had contracted for.

To use less polite language, debt management tends to find excuses for a pussyfooting policy. A good corrective for these excuses is Henry Simons' slogan that the justification of interest is to compensate people for accepting illiquidity, and it is never justifiable to give them interest and liquidity, too—at least *ex ante*. Let me urge more candor in dealing with these problems.

Turning to Mr. Youngdahl's paper, I am inclined to share in the rejoicing over the revival of monetary policy and to agree that Federal Reserve policy has been unusually successful since 1951. But a few reservations should perhaps be registered.

To begin with monetary policy in 1951, this looks better by hindsight than it did at the time. Chairman Martin, two months after the accord, still pictured inflationary pressure as critical in his statement before the House Banking and Currency Committee on the extension of credit powers granted in 1950; and six months after the accord, the *Federal Reserve Bulletin* was still insisting on the need of a "vigorous program of fiscal and credit restraint." Yet under the terms of the accord, the Federal Reserve did not stop increasing its holdings of government securities until October, 1951, and the deposit-supporting power of owned reserves (total reserves less rediscounts) was 5 per cent greater in the fourth than in the first quarter of 1951. Certainly the Federal Reserve was doing at least fairly well by any standards. But speaking as an outsider, without benefit of the files Mr. Youngdahl has evidently reviewed, it seems to me that the Federal Reserve was running a risk, and that

an ideal monetary policy would not have ridden with quite so slack a rein.

By the test of the deposit-supporting power of owned reserves, the Federal Reserve began to tighten in 1952 only in the autumn and turned around in mid-May of 1953. Since the downturn of 1953 is pretty clearly dated in July, this record is a little too good as a response to the weakening of business; and inventories (one of the major criteria invoked by Mr. Youngdahl) were still rising fast. As Mr. Youngdahl intimates, the Federal Reserve was reacting to money market symptoms more than to the general situation. After refusing for some months to respond to the Federal Reserve's mild credit restriction measures, most interest rates began to firm in March—presumably because of uncertainty induced by Treasury financing—and the suddenness of the rise made it natural to ease the market.

As I remarked in relation to Mr. Robinson's paper, I feel some regret that the Treasury and Federal Reserve backed off so easily from the program of lengthening debt maturities. It might have been better to have eased the market enough earlier than mid-May to give the new bond issue a favorable launching and to have taken the occasion to feel out the effect of substituting a mixture of bonds and cash for intermediate-length maturities.

Mr. Youngdahl is scrupulous not to claim too much for monetary policy in relation to the recession that started in 1953. This is a case where it would be easy to prove too much. The Federal Reserve took measures calculated to lower the cost and increase the availability of credit. In the field where we have most to hope from lower rates of interest and relaxed capital rationing—namely, construction—a powerful support for activity has developed. The effect seems a bit too dramatic for the apparent cause. The fact that an increasing share of the flow of savings is channeled through institutions that insist on placing it in securities and mortgages must be a factor in the situation. But it is no mere coincidence that easy money has been accompanied by a strong security market, facilitating corporate and municipal flotations, and pushing institutional investors toward mortgages. Monetary policy may not be the source of all economic blessings; but it is proving more helpful than most of us would have guessed a few years ago—undoubtedly largely because of skillful handling.

EARL R. ROLPH: Professor Robinson has traced for us some of the patterns of war finance that have recurred through the past three major conflicts this country has waged. War results in substantial increases in government expenditures for goods and services and in large deficits. Together these create the inflation potential that explodes into large increases in private expenditures and, except during World War II, into large increases in prices. The government's large financial requirements during wartime lead to an apparent shortage of money—a situation which Secretaries of the Treasury manage to overcome by technically brilliant financial maneuvers. These maneuvers have taken different forms but they are alike in resulting in large increases in the amount of money in private hands. Secretary Chase was driven to the "unsound" procedure of openly printing greenbacks. So ashamed was he of this breach of financial decorum that later, as Supreme

Court justice, he declared his own actions unconstitutional. Nothing so embarrassing was required of the Secretaries during the last two great wars. Money was created, of course, and on a large scale. The Treasury first printed the debt and pursuaded others to create the money.

A recurring theme of war finance stressed by Professor Robinson is the adoption of the tactics of high-pressure salesmanship to sell the debt. Chase was clearly outclassed by Glass and Morgenthau on this score, not that he was niggardly in his efforts. Here we find no great change in the economic ideas of Treasury officials. Success of a bond campaign was judged and is still judged by the test of the volume of business. Failure means that some of the Treasury's merchandise remains on the shelves. So strong was this conception of success that, during World War II, the Treasury consistently underpriced its securities, creating a spread between the sales prices and the support price. The enterprising souls who stood in line to accept these gifts from the Treasury were called "free-riders"; they were also called other names.

The condensed survey that Professor Robinson has just related reveals some change in official ideas, too. In every major war in this and other countries, finance officials have been plagued by the reluctance of some people to buy bonds immediately, preferring to wait for what they hoped would be a better deal. Whether officials should allow this consideration to bother them is a nice question that has a definite answer only if it is assumed that the sale of more debt is better than the sale of less. The corrective technique discovered was, as everyone knows, the practice of having the central bank support the prices of government securities. Secretary Chase had no central bank to perform this operation for him, and he thereby probably spared the country from even more inflation than did occur. Secretary Glass had recourse to the device of supporting the prices of earlier issues by fixing their rates of conversion into later issues—a somewhat clumsy technique even in the most skillful hands.

The fundamental question of debt management during wartime under modern conditions concerns what economic function it is supposed to perform. Finance officials have been almost obessed with the idea of raising money. But of course a sovereign government always has access to unlimited financial means. Presumably the economic purpose is to force or persuade people to buy debt instead of buying goods and services. But the apparatus of direct controls has made this purpose largely obsolete. Scarcely anyone can be found who believes that the 2 per cent yield of World War II made any important difference. In any event, there exists a much simpler method of preventing private borrowers from taking advantage of low rates of interest. A tax could be imposed on borrowers in amounts equal to, say, 10 per cent of the proceeds of any loan and collectible at the source by the Federal Reserve banks. We can have the advantages of a 10 per cent war without the Treasury troubling itself to sell debt at all. The gains of such a system are many. Not the least would be that of sparing the country the exhortations of bond salesmen. Another would be the reduction in the vast amount of paper work involved in turning the Treasury into a savings bank. Professor

Robinson apparently takes the view that debt management has a role to play in an all-out military effort. I think he is mistaken. The best system of debt management during such a period is no debt management at all. If it is objected that the resulting flood of money would create postwar problems, the answer is that there exists no method, except much heavier taxation than any country has seen fit to impose, to avoid postwar problems. With no wartime debt management, it is unlikely that we would again handcuff ourselves because of fears of postwar deflations.

Mr. Youngdahl has presented an interesting abbreviated history of monetary policy since the accord. I find myself somewhat out of sympathy with the tone of Mr. Youngdahl's remarks—I mean with his interpretations of the evidence, not with his account of the evidence. I detect a note of misplaced complacency. We are told that "the old instruments and principles of reserve banking have again proved themselves in use to be effective and sound." The word "again" should be sufficient to give anyone pause. When was it that the old instruments proved themselves so effective? The history of the Federal Reserve is not one of striking successes. Even if we limit our attention to the postwar era, there have been failures. It should be recalled that it was the Federal Reserve officials who decided to offset the deflationary effects of the Treasury surplus during the immediate postwar years. It is customary but not convincing to place the responsibility for these policies solely upon the Treasury. The policy of supporting the structure of yields on federal securities was vigorously supported by officials of the Federal Reserve System before Congressional committees and in the public print. Not even the Treasury can be charged with the incredible policy of supporting the bond market in reverse during the recession of 1949. But let us be careful about blaming anyone but ourselves—professional economists—for these policies. We failed to speak with a clear voice when it mattered.

The restoration of the old tools of monetary management since the accord have consisted, according to Mr. Youngdahl's account, of restrictions on bank borrowing, supplemented by open market operations and changes in legal reserve requirements. Instead of supporting the prices of Treasury obligations, the Federal Reserve has supported the prices of bankers' obligations. To a simple-minded person like myself, there seems to be no vast difference between these and former practices. Let us be clear that bank borrowing from the Reserve banks is inflationary; it is another way that banks obtain reserves. Youngdahl stresses the point that banks are reluctant to borrow. When circumstances beyond their control force them into debt, they stop increasing, or is it that they merely increase less rapidly, the quantity of money in private hands. No doubt it is true that banks are reluctant to borrow, but like many ordinary persons, bankers allow their reluctance to be overcome by more attractive alternatives. Mr. Youngdahl has pointed out that the yields on some classes of short-term securities move together with the discount rate. This fact suggests that the reluctance to borrow is conditional; it depends upon the foregone gain of other methods of obtaining reserves. The technique of relying upon some automatic tendency on the part of banks to adjust their asset positions to the level of their indebtedness seems to me to be

dangerous. It permits the public and the banks to determine monetary policy, and this, I think, is the fundamental objection to the earlier policy of supporting the government bond market. The elimination altogether of the privilege of banks to borrow from the Reserve banks seems to me to be a desirable reform.

During the mild recession we have been experiencing, the Reserve officials have not exhibited the aggressiveness that someone who believes in vigorous monetary policy would like to see. One could even debate whether the Federal Reserve System has allowed the expansionary effects of the federal deficit to exercise its full influence on private expenditures during the period since the fall of 1953, when the evidence was reasonably clear that the economy was in a decline. Imagine, if you will, what the situation might have been if the Treasury had possessed a very large cash balance at that time and had, instead of selling debt, allowed its cash balance to fall by the amount of the deficit. Imagine further that the Federal Reserve had simply allowed this cash to flow into the hands of the public, leaving reserve requirements and the discount rate unchanged, and had engaged in no open market operations. Such a policy is neutral in the sense that monetary management exerts no independent influence on private expenditures. This criterion of neutrality rests upon the belief that the Federal Reserve cannot take responsibility for the automatic flexibility of the tax system nor for other features of fiscal policy. Would the effect on the spending behavior of private groups have been less stimulating in this event than that of the policies actually pursued? From this point of view, it is generous, I think, to hold that the Federal Reserve has adopted even a neutral policy to offset the recession. It is true to be sure that the policies adopted have not been as restrictive in fact as they might have been.

On the subject of economic stabilization, there is nothing much more dangerous than to suppose that we have at long last in this country a body of monetary and fiscal devices adequate to the task of preventing large swings in private expenditures. We do not as yet have even a deliberate synchronization of fiscal and monetary policies. Mr. Youngdahl notwithstanding, the old principles of monetary management are no longer good enough.

TAXATION AND INCOME DISTRIBUTION

THE DIFFERENTIAL TAX BURDEN ON STOCKHOLDERS

By DANIEL M. HOLLAND
National Bureau of Economic Research

Introduction

This is a report on some of the findings of a study I have been undertaking at the National Bureau of Economic Research.[1] I shall place major emphasis on the conceptual framework of my project and its findings; the discussion of assumptions and procedures will, perforce, be cursory, but I must warn you that the findings are highly qualified—valid only within the premises and techniques used in their derivation. An analysis of our method and its limitations will be found in the full report now in preparation at the Bureau. Undoubtedly, too, many of the qualifications will be brought out by the discussants. The primary limitation, however—our assumption that the corporation income tax is not shifted—deserves specific mention at the outset.

My investigation is concerned with estimating the income tax load on stockholders and the degree of differential taxation to which they have been subject. This is a matter that aroused great controversy and about which there appeared to be much misunderstanding in the discussions of the relief provision of the Internal Revenue Code of 1954.[2]

[1] This study was initiated under the guidance of the late Robert Murray Haig, to whom I am deeply grateful for both advice and encouragement. It has been the beneficiary of searching critical readings, at one stage or another, by Arthur F. Burns, Lawrence Seltzer, Carl Shoup, Richard B. Goode, W. Leonard Crum, Geoffrey Moore, Richard Slitor, and Thor Hultgren. In addition an earlier version of the study has been read by Leo Wolman, Simon Kuznets, Dan Smith, Gerhard Colm, William S. Vickrey, A. G. Hart, C. Lowell Harriss, Maurice E. Peloubet, Marshall Robinson, and C. Harry Kahn. To these men my deepest thanks. It should be understood that this does not mean to imply that they supported my point of view or my procedures. Quite the contrary in a number of cases Nor do I mean to "socialize" the blame. All errors and oversights are mine alone. For helpful advice and computation assistance in the earlier stages of the project, I wish to thank Bella Shapiro, Gloria Moskowitz, and Fred Stewart. Finally I am most grateful for the critical insight of Doris Eiseman and Mary Ann Zimmerman, who, in addition to doing most of the computations, helped me clarify a number of conceptual problems.

[2] The author does not claim, of course, either to have cleared up all the ambiguities or difficulties of this problem or to have blazed a trail in isolating the relevant considerations. A number of investigators have worked in this area. Among the most substantial contributions are: Richard B. Goode, *The Corporation Income Tax* (John Wiley and Sons, 1951) and *The Postwar Corporation Tax Structure* (Treasury Department, Division of Tax Research, 1946) W. L Crum, "The Taxation of Stockholders," *Quart. Jour. Econ.* (February, 1950); also, the *Preliminary Report* and *The Final Report* of the Committee on the Federal Corporate Net Income Tax, Harold M. Groves, Chairman. The *Preliminary Report* was made in 1949 and the *Final Report* in 1950 to the National Tax Association, which had established the Committee, at the Association's annual meetings.

How Heavily Are Stockholders Taxed?

While it is generally agreed, if the incidence of the corporation income tax is taken to be on profits, that stockholders compared with other persons are subject to a differential tax load, there are divergent points of view about the nature and relative weight of this differential burden. Some critics, placing the emphasis on distributed corporate earnings, point to the fact that they are taxed first at the corporation level when earned and again at the personal level when distributed and contend, therefore, that this source of income is "overtaxed." This was one of the reasons cited by President Eisenhower for the relief provision recently incorporated in the Internal Revenue Code of 1954. (*Congressional Record,* Volume 100, No. 11, Eighty-third Congress, 2nd Session, page 549.)

Others, however, concentrating on the undistributed segment of corporate earnings emphasize that this income source escapes its fair share of taxation, because it is not subject to the high marginal rates of personal income tax that would have applied had it been distributed to stockholders. Such was the emphasis of President Roosevelt's initial proposal of an undistributed profits tax in 1936. (*Congressional Record,* Volume 80, Part 3, Seventy-fourth Congress, 2nd Session, page 3146.)

Clearly, the considerations raised by both points of view are relevant in the determination of the differential tax load on stockholders; the final answer rests on the relative strength of these two factors. Either contention—i.e., primarily overtaxation or primarily undertaxation—can be proved by an appropriate set of illustrative figures. This being the case, it seemed sensible to use the most realistic data available: the data of *Statistics of Income,* the annual Bureau of Internal Revenue tabulations from tax returns.

Our Procedure

Basic to our "standard" method is the assumption that the corporation income tax rests on profits. While no unanimity of opinon exists on this score, the view that the tax is not shifted, particularly in the short run, is still most widely held. Moreover, it is the view germane to any contention that stockholders are differentially taxed. (Not to be dogmatic, however, we present below the results from an alternative calculation that assumes half the tax is shifted.)

Central to our procedure, also, is the assumption that in all income classes, stockholders' share of corporate earnings before tax can be determined by a proportionate allocation based on dividend receipts. So from the aggregate data on pretax corporate earnings we can obtain a ratio by which to "blow up" dividend receipts to pro rata shares of net corporate earnings. (Hereafter, unless otherwise specified, the

phrase net corporate earnings refers to corporate income before taxes; i.e., the sum of dividends, corporate savings, and corporation income taxes with corporate savings taken net of deficits.)

Then from a cross-classification for dividend recipients (stockholders) of income class and dividend size class we break up the array of stockholders into some 225 cells. For example, from this array we get an entry for stockholders with adjusted gross income of $4,000 and under $5,000 with dividend receipts of more than zero and less than $100, another for those at this same income level with dividend receipts of between $100 and under $200, etc. To the average amount of dividends in each of these cells we apply the corporate earning multiplier and add this product to stockholders' average adjusted gross income. We call the result imputed gross income. It includes all of net corporate earnings rather than dividends as the measure of personal income from corporate activity.

Next, stockholders and the data relevant to them are rearrayed in new income classes based on the size of their imputed gross income. We strike averages for these classes, plot them, and obtain a schedule from which to read off the relevant data for a number of selected imputed gross income levels from $1,000 to $500,000. To measure the degree of differential taxation we break down net corporate earnings into two components: earnings for distribution (i.e., the sum that had to be earned, in view of the corporate tax, to enable the actual amount of corporate dividend payments) and earnings for retention defined, similarly, as the pretax counterpart of retained earnings.

We address ourselves first to the double taxation of distributed earnings (earnings for distribution). In this connection the "extra burden" on stockholders is measured by the excess of the sum of the corporate tax on earnings for distribution and the personal tax on dividends over the potential personal income tax on earnings for distribution. The extra burden expressed as a fraction of its base we call the differential, and in this case it is equal to $C\ (1 - P)$, where C equals the corporate rate and P the relevant personal marginal rate. Since P rises with stockholders' income but never reaches 100 per cent, the differential against the earnings for distribution segment of the stockholder's share of net corporate earnings falls as the level of stockholder income rises, but always remains positive.

But this is only part of the story. What about the undistributed segment? Here the extra burden equals the corporate tax on earnings for retention minus the potential personal tax on this same base. Expressed as a fraction of earnings for retention this comes to $C - P$. (This P is, of course, higher than the P in the earnings for distribution formula; the C is, also, because earnings for retention are taken net

of deficits.) In this case, depending on the relative heights of C and P, the differential can be positive, negative, or zero. With C invariant with stockholders' income and P a rising function thereof, the differential will decline as stockholder income rises, and after a point, if P is high enough it will (and in most of the years of the decade of the forties did) become negative, turning into a tax "benefit."

A combination of the two measures we have just discussed provides the composite or net result: the differential against net corporate earnings, which is a weighted average of the differential against each of the components of net corporate earnings.

Let D be earnings for distribution and R earnings for retention. Then the differential against net corporate earnings equals:

$$C\,(1-P)\frac{(D)}{(D+R)} + (C-P)\frac{(R)}{(D+R)}$$

It will be a declining function of stockholders' income. Further, after a point the differential against earnings for retention can (and in most years of the last decade did) weigh so heavily that the extra burden on net corporate earnings will become negative. In other words, at incomes above some high level an income tax differential in favor of net corporate earnings will prevail.

By this measure we can answer the question: How much more (or less) heavily were corporate earnings actually taxed than they would have been had they been subject in full to the personal income tax alone?

We have used one more measure in our analysis. By relating the extra burden to the total income of stockholders, we obtain the differential against (or in favor of) stockholders. With this measure we answer the question: How much more heavily, measured in terms of effective rates, were stockholders actually taxed by the combined corporate-personal income tax system than they would have been with the corporate tax abolished and their pro rata share of net corporate earnings subject fully and promptly to the personal income tax?

Let O be stockholders income from sources other than corporate earnings, then the differential against stockholders equals:

$$C\,(1-P)\frac{(D)}{(D+R+O)} + (C-P)\frac{(R)}{(D+R+O)}$$

One further point about our measures. It can be argued that some portion, at least, of retained earnings would show up as capital gains, and that some of these gains, in turn, would be realized in taxable form, and thus sometime in the future an additional personal income

tax liability would be incurred. In measuring the actual tax load on earnings for retention, therefore, we added a term representing the estimated present value of this future capital gains tax liability. Needless to say, the adjustment is not very precise. In any event, it is relatively minor.

So much for the conceptual framework. Now what have we found out?

The Findings for a Selected Year—1950[5]

Our basic data—the tabulations in *Statistics of Income*—come out with a lag of several years; 1950 is as contemporaneous as we can get. How heavy was the differential taxation of net earnings and stockholders in this year? The answer is summarized on Chart I.
CHART I. DIFFERENTIALS, 1950

From an examination of line 1 it appears that the double taxation of distributed earnings was substantial. At the bottom of the taxable stockholder income scale, for example, earnings made for distribution to stockholders were subject to a tax liability over 34 percentage points higher than would have been their due under the personal income tax

[5] The findings presented here and in what follows are preliminary. They are the result of numerous calculations all of which have not yet been checked. However, it is unlikely that the arithmetic errors that will be uncovered will change our results substantially. The entries in Chart 1 and Tables 1, 2, and 5 are weighted averages of the data for joint and separate returns.

alone. At the $25,000 stockholder income level the net extra burden averaged about 29 percentage points, and at the top of the stockholder income range plotted on the chart ($500,000) it came to 10 per cent. The higher the stockholder income level the lower the differential against earnings for distribution.

While the differential against earnings for retention follows the same general pattern, the magnitudes involved are smaller and its fall is sharper. This is most apparent over the upper portion of the stockholder income array. Starting at 30 per cent for the lowest income stockholders, it fell very rapidly, so that by the $25,000 mark it was only 15 per cent; the fall continued, the burden changed to a benefit, and at the top of the stockholder income scale we found a differential of −33 per cent.

The weighted average of these two measures—the differential against net corporate earnings (line 3)—follows, of course, the general pattern of the two differentials that comprise it and falls in between them. Reflecting the greater absolute magnitude of earnings for retention, its value when plotted lay closer to line 2 than to line 1. Over most of the income range, the net corporate earnings component of stockholders' income was "overtaxed," but for stockholders higher up the income scale, "undertaxation" occurred. Very heavy was the extra burden at the lower stockholder income levels—between 31 and 29 percentage points over the span from $1,000 to $10,000. After $10,000 the differential against net corporate earnings fell rapidly, reaching zero at around $100,000 and a nadir of −16 per cent at $500,000 of stockholders' income.

The fact that this component of their income was subject to a differential tax liability means, of course, that stockholders' income *in toto* was either over- or undertaxed. It appears that most stockholders—on average, those whose incomes ranged from $1,000 to $50,000—were liable for a sizable extra income tax liability. (Over this income interval it ran from 6 to 10 additional percentage points of tax.) But as we examine the stockholders near the top of the income scale a different picture emerges, for the differential declined very rapidly after the $50,000 point. Again, as an average result, stockholders with incomes higher than $100,000 enjoyed a tax benefit that became relatively more important the larger their income.

Our findings are for average stockholders; so we have no way of telling precisely how many fell in the over- and undertaxed categories. For 1950, however, we can furnish a reasonable figure on this score, because we had to examine the tax liability in each stockholder cell for our "partnership" method revenue estimate reported on below. Of the 3.4 million double-taxed stockholders, about 3.3 million, or 97

per cent, paid a higher combined corporate-personal income tax liability than would have been due under the personal income tax alone; they were, therefore, overtaxed. On the other hand, some 3 per cent, about 100,000, were undertaxed. While small as a proportion of all stockholders, the undertaxed group assumes greater importance when we measure its share of all double-taxed net corporate earnings. Here, because the distribution of net corporate earnings is highly concentrated, we found that about 46 per cent of net corporate earnings imputable to personal income taxpaying dividend recipients was undertaxed. (In deriving these figures we did not make the future capital gains tax liability adjustment alluded to earlier. However, this does not seriously affect their relevance for the purpose at hand.)

The same measures elaborated for 1950 have been undertaken for all the intervening years since 1940, except 1942 and 1943. It goes beyond the scope of this paper to examine them in detail here. In general their pattern is similar to the fifties, but, of course, the height of the differentials varied considerably over the period.

Two Alternative Assumptions

Our procedure, we recognize, is open to numerous objections and criticisms. At a number of points along the line we made a specific choice from among a number of possible assumptions and, in some cases, at least, strong support can be found for one or another of those alternatives that we failed to select.

In particular, had we chosen a variant assumption on the incidence of the corporation income tax or an alternative definition of net corporate earnings, our results would have been noticeably different from those we have just reported on.

Therefore, for 1947, we measured the differentials on the assumption that half the corporate tax is shifted. From this test one simple conclusion emerges. (See Table 1.) To the extent that the corporation income tax is shifted, our findings based on the standard assumption involve an overstatement of the extra burden on net corporate earnings and stockholders.

Similar accounting conventions are used in defining income for the personal and corporation income taxes. Since we are comparing the actual tax of one system with the potential tax of the other, we did not feel it necessary conceptually to redefine income to take account of the effects of rapid and sharp increases in the price level. However, as a matter of some interest and out of deference to a substantial body of opinion which holds that the BIR definition of income is seriously inappropriate when price levels change rapidly, we undertook an additional alternative calculation for purposes of which we lowered the

TABLE 1

COMPARISON OF DIFFERENTIALS UNDER STANDARD METHOD AND FIFTY PER CENT SHIFTING ASSUMPTION, 1947

Imputed Gross Income Level (000)	Differential Against Net Corporate Earnings			Differential Against Stockholders

total of corporate earnings imputed to stockholders by the inventory valuation adjustment and the estimated excess of current over historical cost depreciation. The results are summarized and compared with our standard method in Table 2.

Our conclusion from this test is that for years of rising price levels, if it is considered sensible and relevant to allow for current costs of inventory maintenance and depreciable asset replacement in defining taxable income, our standard case understates the differential against

TABLE 2

COMPARISON OF DIFFERENTIALS UNDER STANDARD METHOD AND CURRENT COST ASSUMPTION, 1947

Imputed Gross Income Level (000)	Differential Against Net Corporate Earnings			Differential Against Stockholders		
	Standard Method	Current Cost Assumption	2–1	Standard Method	Current Cost Assumption	5–4

500.	−25.8	−5.6	20.2	−23.0	−5.2	17.8

stockholders and net corporate earnings. But the basic pattern of our findings remains. Under the current cost alternative, too, the differentials fall as stockholders' income rises, and, after a point, they turn in favor of net corporate earnings and stockholders.

Revenue Aspects of the "Partnership" Method

Were shareholders to be taxed on their corporate earnings as members of a partnership are taxed on their share of its income, the corporate entity as such would drop out of the picture. Since stockholders would be held accountable under the personal income tax for their pro rata share of corporate earnings, all such earnings would be promptly and fully called to account and subject to only one income tax. Over, under, or unequal taxation of corporate earnings would cease to exist. In what follows it should be clearly understood that we neither support nor condemn the partnership method of taxing corporate earnings, nor do we raise the question as to whether it is in fact a practical alternative. (Some students who admit its desirability in principle question its administrative feasibility.) In addition, we assume, as we have for the most part earlier, that the incidence of the corporation income tax is on profits, and that the same ratio of dividends to net corporate earnings characterizes each of our income class dividend size cells.

For several years—1947, 1949, and 1950—we have estimated the revenue loss or, possibly, gain that would ensue upon the institution of the partnership method. These estimates are of interest in and of themselves, for in a period of heavy federal government revenue requirements, among the relevant criteria for evaluating a proposed change in the tax structure is its revenue effect. More particularly, in the context of our study, these estimates constitute a measure of the aggregate extent of the unequal taxation of stockholders, thereby complementing the differentials which are average measures of experience at selected income levels and, therefore, furnish no idea of the total amount of differential taxation of all double-taxed stockholders.

Our starting point in these estimates was to consider the corporate tax abolished and the revenue it raised lost to the Treasury. How far would the increased personal income tax collections due to full imputation of net corporate earnings go toward recouping this revenue loss? To answer this question we estimated for each of our stockholder cells (i.e., the cells in the cross-classification of income and dividend size class) the increase in personal income tax liability that would follow full imputation of stockholders' pro rata share of net corporate

earnings. (Numerous details are involved in our procedure. All we do here is present its basic features.) We did the same for taxable estates and trusts. The difference between the corporate tax liability sacrificed by shifting to the partnership method and the increase in personal income tax liability constitutes the net revenue loss on a current basis; i.e., that portion of the revenue loss that would occur in the year of the shift to the partnership method.

But this is not the end of the story. A further loss in revenue is to be expected. For, following the treatment now accorded partnership shares, the basis of valuation for the purposes of determining capital gains would be reduced by the full amount of imputed retained earnings. On this score, future capital gains and the tax liability thereon would be lower because of the switch to the partnership method. It goes without saying that the lack of any real evidence germane to this item causes this portion of our estimate to be characterized by a much lower order of accuracy than the current revenue loss figures.

Quite varied are the results for our selected years (see Table 3). In 1947, for example, the Treasury would probably have suffered no revenue loss by a shift to the partnership method, currently. Over the indefinite future, however, tax collections would have totaled between 1 and 1.5 billion dollars less because of the imputed retained earnings of 1947. In 1949, a more sizable current revenue loss would have developed. For 1950, our estimate of the loss runs at a still higher level. The current revenue loss of around 3.5 billions represents a little under 10 per cent of total corporate and personal income tax liabilities. (As tabulated in *Statistics of Income*, the corporation income tax liability in 1950 came to 17.3 billion and personal to 18.6 billions.) To recoup it, something like a 3.2 percentage point upward shift in the personal income tax schedule would have been necessary. Moreover, we estimate a future revenue loss of around 1.4 billion dollars. For 1953, a more substantial revenue loss is indicated: 5.7 billions currently and 1 billion more in the future. To maintain the estimated 1953 level of tax receipts, a rise of four points in personal income tax rates would have been required.

The difference in the revenue loss among these several years is to be explained by variations in the relative heights of the corporate and personal income tax, the magnitude of net corporate earnings, and the proportions represented by dividends and retained earnings.

It seems safe to conclude that only in a prosperous year, with the corporate rate under 40 per cent, the personal rate structure effectively as high as it was in 1947, and a high proportion of corporate earnings retained, would a switch to the partnership method not involve a current loss of revenue to the Treasury.

TABLE 3

PARTNERSHIP METHOD REVENUE LOSS*

(Dollar Amounts in Billions)

Year	Current	Future	Total	Percentage Point Rise in Tax Rates Required to Recoup Current Revenue Loss
1947	0.2†	1.2	1.0	−0.2
1949......	2.2	0.9	3.1	2.5
1950 ..	3.5	1 4	4.9	3.2
1953... ...	5.7	1.1	6.8	4.0

* The 1953 values are considerably less reliable than those for the other three years, for no detailed data pertaining to this year are yet available. Despite this, however, the figures appear in the table because of the interest that attaches to the most recent experience.

† Revenue gain.

The Aggregate Extra Burden

The data assembled in connection with the partnership method revenue loss estimates bear on another problem discussed earlier in this paper. We have already examined the net extra burden of the corporation income tax on average stockholders at selected income levels. Now we can approach it somewhat differently, concentrating on aggregates rather than averages. How heavy an extra burden did the corporation income tax represent in the aggregate? In what follows, this query is answered only in terms of what we have called above the current increase or decrease in tax liability under the partnership method. Unlike the differentials presented earlier, these data take no account of the future capital gains tax liability.

Table 4 presents the relevant information. In every year analyzed, for stockholders in the upper portion of the income array, the partnership method would have meant a heavier tax liability than they actually were subject to. These stockholders, then, in the aggregate, even though double-taxed, were undertaxed. On the other hand, stockholders in the lower portion of the distribution were overtaxed. Had a switch to the partnership method been made, their income tax liability would have been lower. By far the larger portion of stockholders were overtaxed, but a not insignificant number in some classes were undertaxed. (See column 6.) Much larger, however, is the proportion of net corporate earnings falling in the undertaxed category. In 1950, for example, as already noted, this came to about 46 per cent.

The Relief Provisions of the Internal Revenue Code of 1954

Very recently what has been described by its proponents as a

* The fact that in 1947 taxable dividend recipients would have probably had a higher income tax liability under the partnership method than under the combined corporate personal income tax system is not inconsistent with our findings that, on a current basis, no increase in revenue would have accompanied a change to the partnership method. Nor are the virtually identical tax liabilities for taxable stockholders under the two systems reported in Table 4 for 1950 a contradiction of our conclusion that in that year a sizable revenue loss would have occurred immediately upon the introduction of the partnership method. For not all dividends show up on taxable returns. For these two years, we were able to trace only between 82 and 83 per cent of net corporate dividend payments to the taxable returns of individuals and estates and trusts. For a variety of reasons—provisions of the tax law, oversight, dishonesty, etc.—the remaining 18 per cent does not get into the personal income tax mill. So the partnership method tax base was only 82 per cent of the corporate tax base.

"significant step in the right direction"[4] has been taken to afford stockholders some relief from the double taxation of dividends. Under the provisions of the Internal Revenue Code of 1954, the first $50 of dividends received from domestic corporations (the first $100 for joint returns) is excluded from taxable income, and further, stockholders are given a credit against personal income tax equal to 4 per cent of the remainder of their dividend receipts. (Internal Revenue Code of 1954, Public Law 591, Chapter 736, Sections 34 and 116. This is considerably less generous than President Eisenhower's original proposal which called for exclusions double the size finally settled on and a tax credit ultimately to reach 15 per cent.)

Thus relief is provided only for distributed earnings and it therefore deals with only a portion of the problem of the differential taxation of corporate earnings. (Apparently, also, no relief is afforded dividend recipients who are not subject to the personal income tax.) But even when viewed more narrowly within their own framework, i.e., from the point of view of distributed earnings only, these relief provisions do not appear to be a particularly satisfactory "step in the right direction."

We have pointed out above that as regards earnings made for distribution to stockholders, the corporation income tax constitutes a net extra burden equal to $C(1 - P)$. The higher the stockholders' income, the lower the extra burden of the corporation income tax. The relief provisions of the Internal Revenue Code of 1954, however, are not geared to this relation. The tax credit, by providing a constant amount of relief at all income levels, operates in such a way that a greater degree of relief is obtained the higher the stockholders' income level, and the relief provided by the exclusion is a rising function of stockholders' income.

More specifically, the credit is equal to 4 per cent of dividends. Since the extra burden falls as stockholder income increases and the credit is the same absolute amount per dollar of dividends at all income levels, the higher the stockholders' income, the greater the proportion of the extra burden removed by the tax credit. As for the exclusion, the relief it affords ranges under 1954 rates from 20 cents to 91 cents per dollar of dividends, the amount of relief increasing with the marginal rate of personal income tax.

So far our discussion of the relief provisions has run in terms of marginal dollars of earnings for distribution. The over-all result, however, is a more complicated story, because it depends on how heavily each relief provision is weighted in the total relief granted, and this,

[4] Remarks by Marion B. Folsom, Under Secretary of the Treasury, before the American Management Association, Hotel Statler, New York City, August 19, 1954.

in turn, depends on the absolute size of the dividend (or earnings for distribution) component of stockholders' income. Per dollar of dividends, the exclusion gives greater relief at all income levels. However, its absolute amount is limited.

To determine how much relief, all things considered, will be provided by the Internal Revenue code of 1954, we applied its provisions to our "average" stockholder data for 1950, this being the most recent year for which the necessary tabulations are available. Our findings are presented in Table 5. (The reader is reminded that stockholder incomes include the retained as well as the distributed portion of net corporate earnings.) The relation between the degree of relief and stockholders' income is U-shaped. Proportionately the greatest relief occurs at the bottom and top of the income scale, with a lesser degree of amelioration

TABLE 5

ESTIMATED REDUCTION OF NET EXTRA BURDEN ON EARNINGS FOR DISTRIBUTION DUE TO RELIEF PROVISIONS OF INTERNAL REVENUE CODE OF 1954, USING DATA FOR 1950

Imputed Gross Income Level (thousands)	Differential Against Earnings for Distribution		Reduction in Differential Due to Relief	
	Before Relief	After Relief	Absolute (percentage points)	Relative (per cent)
1	2	3	4	5
$ 1	34.1	24.1	10.0	29.3
2	34.1	26.4	7.7	22.6
3	34.1	27.6	6.5	19.1
4	33.7	27.4	6.3	18.7
5	33.8	28.3	5.5	16.3
6	33.9	28.8	5.1	15.0
8	33.7	29.9	3.8	11.3
10	32.8	29.3	3.5	10.7
12	32.6	29.3	3.3	10.1
15	32.1	29.1	3.0	9.3
20	30.8	27.9	2.9	9.4
25	29.2	26.3	2.9	9.9
50	24.9	22.3	2.6	10.4
75	21.7	19.2	2.5	11.5
100	19.1	16.6	2.5	13.1
150	16.7	14.2	2.5	15.0
200	14.6	12.2	2.4	16.4
250	13.2	10.8	2.4	18.2
500	10.0	7.6	2.4	24.0

in between. (See column 5.) For the lower average stockholder incomes where the absolute amount of earnings for distribution is small, the exclusion, which gives more relief per dollar of dividends, far outweighs the credit in importance. Hence the relatively high degree of relief observed. Near the top of the income scale the strength of the relief is explained by the fact that the differential against earnings for distribu-

tion becomes steadily smaller as the size of stockholder income increases, while the absolute amount of relief is substantially the same as at lower income levels. (See columns 2 and 4.)

In summary, our major conclusion is that the relief provisions of the Internal Revenue Code of 1954 are inappropriate measures for the hardship they seek to alleviate. They are not geared directly to the basic feature of this hardship; viz., that it becomes increasingly less severe the higher the marginal personal income tax rate to which stockholders are subject. It is true that because of the relative weights assigned the exclusion and tax credit, we do find that the absolute amount of relief (measured in percentage points) is greatest at the smallest incomes and least at the top of the income scale, and that for "representative stockholders" in the lower portion of the income range the relative degree of relief is higher the greater the need for it. But, over the rest of the income scale, from about the $15,000 point on up, the opposite condition exists: the less stockholders need it, the greater the degree of relief they obtain.

One final comment. Were Congress, at some time in the future, to continue to step in the right direction and increase the exclusion and/or tax credit, complete removal of the differential burden could be accomplished for stockholders at only one income level. Those below this point would remain overtaxed; those above this income level would be undertaxed. As a corollary point, it must be recognized that if the relief afforded by a given credit and exclusion level is deemed satisfactory and just, any change in the corporate income tax rate or personal income tax rate schedule would disturb this equilibrium and necessitate a readjustment of the size of the exclusion and credit.

THE INDIVIDUAL INCOME TAX AND INCOME DISTRIBUTION

By PAUL J. STRAYER
Princeton University

The effects of the individual income tax upon income distribution have been made the subject of increasing attention in recent years. Pechman's recent study and the detailed analysis of the upper income groups by Kuznets have substantially increased our knowledge in this area. Musgrave and others have made useful estimates of the distribution of the tax burden among income classes. In almost all these studies[1] emphasis has been placed upon the effect of the individual income tax upon the aggregate income distribution. In this paper I propose to consider some of the effects of the income tax upon individuals with equal incomes and the consequences of the uneven impact of the tax upon both the final income distribution and the equity with which the progressive rates apply. Although equity, in the sense of equal treatment of persons with equal incomes, is generally conceded to be an objective of the income tax, the bias toward more equal income distribution has tended to minimize the attention given the gross discrimination possible under the law as it now stands. It is the contention of this paper that current practices are so bad as to seriously weaken the income tax as a means of income redistribution and to threaten its future as the largest single source of federal revenue.

The individual income tax has been long considered one of the most effective instruments of taxation because, in addition to its use as a means of equalizing incomes, it has the advantages of countercyclical flexibility, relatively certain incidence and the ease with which it can be adjusted to take account of family size, and other considerations which seem to bear upon taxable capacity. As a result, the increased use of this source of federal revenue has been generally favored. In the relatively short period since 1913, the yield of this tax has increased so that it now produces approximately 45 per cent of all federal revenues. This has been accomplished by raising the rates applicable to individual incomes and greatly increasing the tax base by drastically lowering the value of the individual exemptions. The importance of the reduction in exemption levels is illustrated by reference to the increase in number of returns from approximately four million in 1934 to

[1] Joseph A. Pechman, "Distribution of Income Before and After Federal Income Taxes, 1941 and 1947," *Studies in Income and Wealth*, Vol. 13 (New York, 1951); Simon Kuznets, *Shares of Upper Income Groups in Income and Savings* (New York, 1953); R. A. Musgrave, J. J Carroll, L D. Cook, and L. Frane, "Distribution of Tax Payments by Income Groups: A Case Study for 1948," *Nat. Tax Jour.*, March, 1951, pp. 1-53.

approximately fifty million in recent years. It can now be said that there are relatively few gainfully employed who do not have to pay some income tax.

A superficial review of the change in the relative role of the individual income tax suggests to many that substantial progress has been made in achieving justice in the distribution of the tax burden as among equals. Although there is a very vocal group which insists that the equalization aspects of the income tax have been carried too far and have led to the destruction of work incentives and investment incentives, no objective analysis of this question can produce evidence to support their contentions.[2] Some qualifications about the adverse long-run implications of continued high rates upon incentives have been made but the extraordinary prosperity and investment boom which has characterized the period since the income tax schedules have reached record levels is evidence that the fears of the opponents of the tax are exaggerated to say the least.

What *is* of concern is that at the same time that the individual income tax has grown to play such an important role in our revenue system it has been made increasingly arbitrary and erratic in its application. As a result, the progressivity of the tax is more apparent than real. Thus, although much is said about the severity of the marginal rates, the recent Harvard studies of top executives bring out the fact that when net capital gains are included in income no one of them paid as much as 50 per cent of his true income in taxation in 1946 and that progression stops at approximately the $50,000 level.[3] It should be noted that these computations are made from Treasury tabulations and do not allow for such items as tax-exempt interest, percentage depletion in excess of cost, and personal consumption expenditures deducted as business expense.

An analysis of the reasons for the difference between the apparent severity of the tax and its actual impact will be considered below. It is important to realize that as now applied the individual income tax is not as effective an instrument of income redistribution as generally believed and that the results of the uneven application of the tax may seriously distort the way in which business is organized and the channels into which investment funds are directed. (J. Keith Butters, *op. cit.*) If these trends toward the emasculation of the income tax continue, there is danger that the cumulative reaction against the arbitrary and capricious application of the individual income tax will destroy its effectiveness. One danger is that there will be a marked increase in

evasion and noncompliance, further aggravating the difficulties we now face. Another danger is that the current tendency of Congress to extend the avenues of avoidance and legal escape will be accelerated.

Before the extent of the deficiencies of the individual income tax are described in detail, the distinction between this analysis and that usually found in general discussions of the effect of the income tax upon income distribution must be made clear. In the usual study, the sole objective is to describe factually the manner in which incomes are distributed before and after taxes. Although an attempt is usually made to adjust the income concept used to take account of certain limitations of the tax law, averages for each income class are used and no attempt is made to indicate the range of tax liabilities to which individuals of the same income class may be subject. There is usually no attempt to measure the extent of avoidance of income tax liabilities. Most studies exclude net capital gains from income so that the data will conform to the concept of income used for purposes of national income measurement. In no case do estimates adequately take account of the influence of accrued income—particularly realizable but yet unrealized capital gains and losses! Similar deficiencies exist in the estimates of net income due to questionable use of expense allowances and other deductions from gross receipts. Thus if, as is the contention of this paper, the effect of existing tax law and administration is to encourage taxpayers to find means of reducing taxable income without substantially reducing their real income, all estimates of changes in income distribution in recent years must be qualified to the degree this has been true. If, as also is the contention of this paper, the possibilities of avoidance of taxation are more extensive in the upper income brackets than in the low, studies based upon income tax returns will show an artificial income distribution both before and after taxes.
